I was here yesterday and heard Mr. Powers' testimony. It is true with respect to me as with respect to him that I am not qualified and have not attempted to be qualified to give an expert opinion on the future economics of this country and future prices. I have not attempted to make any economic study of future prices. I have been instructed to use the prices as of June 1, 1939.

(Objection by Commission Counsel to further testimony with respect to prices beyond 1939, motion to strike all testimony to this point on that subject, objection to such line of examination, and motion to strike testimony on ground that it is purely speculative and does not concern itself with the reasonably immediate future overruled and motions denied.)

Cross-Examination Interposed by Mr. Booth.

The June 1, 1939, prices which are used in this exhibit were obtained largely through our purchasing department, which is in daily contact with vendors of such materials as are included in this exhibit.

Direct Examination Resumed by Mr. Hedrick.

I secured that information through the purchasing department of Natural Gas Pipeline Company.

Referring to page 3 of Exhibit 97, the retirements on that page are retirements of property to be retired on account of renewal or installation of property shown on page 2, which takes the place of the property retired shown on page 3, and the asterisks on page 2 refer directly to items on page 3. In other words, the second item on page 2 shows an expenditure in 1944 of $43,020 for renewal of Griscom Russell Bentube Gas Cooling Sections, and the book cost of the Griscom Russell Bentube section which will be retired at that time is $27,794.

Cross-Examination Interposed by Mr. Slaff.

The term "reclaimed" is used because that is a term which is normally used when making retirements from capital investment. It does not necessarily mean reclaim in the sense that there will be salvage. On some of the items on which retirement or reclaim is shown, there is salvage. It is used on page 2 in the sense of being synonymous with the word "retirement."

620 (The Examiner here made the inquiry of whether the term "reclaim" is a variable term in the accounting department of defendants. He stated that in Mr. Powers' case the words "retirement" and "salvage" were used, and inquired whether the word "reclaim" appeared in one sense in one place and other words appeared in other places, and whether its appearance here depended upon the fact that at one time they thought they would have salvage value and other times would not. Counsel for defendants thereupon stated that he might be responsible for that; that they had been in a considerable hurry to get these exhibits prepared, and after this exhibit had been mimeographed he noticed the word "reclaim" instead of "retirement" but told Mr. Davidson not to have the page remimeographed, as counsel could explain, as Mr. Slaff suggested, that the words are synonymous.)

Question by the Examiner.

When I used the term "reclaim" I did not think there was some salvage connected with the items which I subsequently decided there would not be.

Direct Examination by Mr. Hedrick Resumed.

I am not an accountant.

On page 3 is a sub-heading, "Salvage." Item 2 shows that on account of the water wells that will be installed at Station 2 in 1946 there will be a salvage value from a well retired to the amount of $2,559, and so on throughout the balance of the page. That salvage is figured at the actual cost as shown by the books of the company for that particular equipment.

(Counsel for defendants thereupon stated that, as he understood it, when casing is taken out of a water well and put into another well, it is charged into the capital investment in the second well at its actual cost as reflected by the books; that it is not salvage in the sense that they are going to talk about at the next session; and that it is just a bookkeeping term which counsel is informed will be included in the bookkeeping requirements promulgated by the Federal Power Commission in 1940. Counsel also stated that it was intended to put the secretary of the Company on to explain some of those bookkeeping details.)

Referring to page 4, Mr. Powers testified yesterday to similar items referred to under Items 1, 2, 3 and 4, and the testimony given by him as to the necessity for those capital expenditures is the same explanation as I would give so far as the stations under my supervision are concerned.

Item 1, entitled "Replace Nugent Oil Filters with Cuno Oil Filters," at an expenditure of $4,386 in the year 1939, will be made at all stations Nos. 2 to 10, inclusive.

Item 2, entitled "Convert Worthington Air Filters to Water Wash Type," will be installed at Stations 4, 5, 6
621 and 7 in the year 1939 in the amount of $1,600.

Item 3, entitled "Renew Main Engine Air Filters," will be installed at Stations 2, 3, and 4 on 17 units in the year 1944; and at Stations 5, 6 and 7 on 15 units, in the amount of $4,500, in 1945.

Item 4, entitled "Renew Main Engine Exhaust Mufflers," in the amount of $10,968, provides for the renewal of exhaust mufflers on 12 engines at Stations 2 and 3 in 1939. The amount of $32,904 appearing in the year 1940 provides for the renewal of exhaust mufflers on 36 engines at Stations 4, 5, 6, 7, 8, 9 and 10 in 1940.

The book cost of equipment retired from main engines shown at the bottom of page 4 would be explained in the same manner as I explained similar matters on page 3 of this exhibit.

The date used by me in determining prices for labor and material going into the capital expenditures contained in Exhibit 97 was June 1, 1939. I prepared that exhibit.

Referring to Exhibit 97 as a whole, the amounts shown thereon for labor and material and other items going into the additional capital expenditures shown in this exhibit represent my considered judgment at this time, based on prices as of June 1, 1939, and based on the experience which I have gained through my employment with Natural Gas Pipeline Company and other experience arising out of my previous employment. (Objection by Commission Counsel overruled.)

Questions by the Examiner.

In giving my answer I mean that so far as prices enter into it, they are based on prices as of June 1, 1939. I have no opinion regarding prices at all. The amounts are based upon my judgment, using prices as of June 1, 1939. My judgment relates to the amount of material and the quantities which I have used and their necessity from an engineering standpoint. I confined my judgment to the two elements of labor and material. (Renewal of motion by Commission Counsel to strike from record all testimony with respect to prices at costs beyond the year 1939 denied.)

Direct Examination by Mr. Morgan.

The various items of addition and replacement set forth in Exhibit 97 represent my considered judgment, based on my experience in the position I occupy, as to expenditure it will be necessary to make at times not later than those indicated in this exhibit, basing the figures set forth in the exhibit upon prices of labor and upon material and equipment costs as of June 1, 1939.

Everything in this exhibit represents my considered judgment, except the element of prices, which are based upon those furnished me by the purchasing costs as of June 1, 1939.

Cross-Examination Interposed by Mr. Slaff.

I have considered in this exhibit prices as of June 1,
622 1939, but I have not formed any judgment as to what
prices will be in each of the years 1940 to 1954, inclusive.

With respect to Item 10, page 3, the impellers to be retired will be at those stations where the new impellers are to be installed.

Direct Examination by Mr. Hedrick, Resumed.

The impellers will be installed at Stations 4, 5, 6, 7, 8 and 10, and the retirement is also at those stations.

The necessity for the expenditures listed on page 5 of Exhibit 97, for yard piping, buildings and grounds, is the same as that given in the testimony by Mr. Powers with reference to similar items.

Item 1 of those same items, entitled "Jacket 6-inch Discharge Lines," represents an expenditure of $7,311. This work will be performed at Stations 2, 3 and 4 on seventeen units in the year 1940. Like work will be performed at Stations 5, 6 and 7 on fifteen units in the year 1941, in the amount of $6,483. Also like work will be done at Stations 8, 9 and 10 on sixteen units in the amount of $6,897 in the year 1942.

Item 2, entitled "Renew 10 inch Discharge and After Cooler Headers," will be performed at Stations 2, 3 and 4 in the year 1939; 5, 6 and 7 in the year 1940; and 8, 9 and 10 in the year 1941. The amounts as shown in the years 1939, 1940 and 1941 represent the jacketing of the 6 inch inlet and outlet lines for the Griscom Russell gas cooling sections.

In the year 1943 the amount of $8,520 is the cost of renewing the 10 inch discharge and 10 inch after cooler headers at Stations 2, 3 and 4. The amount of $7,320, shown in 1944, is the cost of renewing the same headers at Stations 5, 6 and 7. The amount of $8,520, in 1945, is the cost of renewing the same headers at Stations 8, 9 and 10.

Item 3, entitled "Renew Muffler Drain Line," in the amount of $6,327, is for the renewal of this drain line at all nine stations in the year 1944.

Item 4, entitled "Renew Underground 3 inch Air Line," is the cost of renewing the 3 inch underground air line from the air receivers to the main building at eight stations in 1940.

I am not certain whether Mr. Powers testified as to the renewal of underground 3 inch air lines. There is a 3 inch air line which extends from the air receivers to the main building and is used to pipe air for starting the main engines. The air line was found to be in a bad state of repair at a number of stations. We have removed the air line at Station 2 and reinstalled it overhead. This Item 4 provides for the installation of a 3 inch air line now underground to an overhead location at all the other eight stations.

It is my judgment that, based on the experience which 623 I have gained as superintendent of the compressor stations of Natural Gas Pipeline Company, these items will have to be renewed as of the dates shown. Several of the items occurring on page 5 will undoubtedly need renewing before the dates shown.

My explanation of book cost of property retired is the same as my explanation of book cost of property retired with respect to page 3 of Exhibit 97.

Under the subtitle "Buildings and Grounds, Additional Capital Expenditures," Item 1, to install extensions to main buildings at Stations 2, 3, 6 and 7, has already been completed.

Item 2 is to install door checks on main and auxiliary buildings. My explanation for that is the same as that made by Mr. Powers in his testimony.

Items 3 and 4 are to install Transite roofs on main buildings and on auxiliary buildings. My testimony as to the necessity for this installation is the same as that given by Mr. Powers for similar items.

Question by the Examiner.

The principal element requiring the Transite roof is the corrosiveness from the water cooling tower spray on the one side and the exhaust water spray on the other. There is another factor which I do not believe Mr. Powers mentioned. This building, being constructed of sheet iron, is subject to quite a bit of expansion and contraction as it gets hot and cools off, and that seems to loosen the tie nails where the roof sheets are tied to the purlings.

Direct Examination Resumed by Mr. Hedrick.

The Transite roofs on the main buildings will be installed at Stations 2, 3 and 7 in 1940 at a cost of $11,267, at Stations 5, 6 and 9 in 1941 at a cost of $9,781, and at Station 8 in 1942 at a cost of $3,687. We have installed Transite roofs on the main buildings at Stations 4 and 10 prior to 1939.

We will install Transite roofs on the auxiliary buildings at Stations 4, 7 and 10 in 1941 at a cost of $3,867, at Stations 3, 5 and 9 in 1942 at a cost of $3,973, and at Stations 2, 6 and 8 in 1943 at a cost of $3,997.

Item 2 in the amount of $2,160 is for door checks which will be installed on swinging doors in the main and auxiliary buildings at all stations in 1939.

Item 5 is to install steel bins at warehouses and tool rooms at all stations in 1940, at a cost of $6,120. Mr. Powers testified as to the necessity for the installation of those bins, and my testimony would be the same as his.

Item 6 is to grade and tile manifold area in 1939, at a cost of $3,542. That expenditure will be made at Stations 2, 4, 5, 7, 8, 9 and 10. The installation has been completed prior to 1939 at Stations 3 and 6. In explaining the necessity for that item, I may refer to the photograph
624 designated as Exhibit 96 and explain that the manifold area so defined under Item 6 is that area between the cooling tower, designated as No. 12, and the main building, designated as No. 1, and in which the manifold piping is located, as designated by No. 11.

This area is subjected to constant precipitation, caused by spray falling from the cooling tower. In this area all control valves are located. These valves require frequent manipulation by the operators.

In the original construction of the plant, gravel walks were provided in this area. Those walks have disintegrated over the space of years that the system has been in operation, caused mainly by the frequent necessity of excavating to inspect and repair the piping in that area. This item provides for the installation of concrete block walks to supplant the original gravel walks. These concrete blocks may be removed when such excavation is needed or when trucks are driving in that area for any reason, and they may be replaced at later times.

The tiling is to lower the water table on this constantly wetted area, so that the operation and maintenance of this area will be facilitated.

The expenditure in 1939 for that item will be at all stations, with the exception of Stations 3 and 6, at which the installation has already been made.

Item 7 is entitled "Gravel Area Around Exhaust Stacks," with an expenditure in 1940 of $1,121. Mr. Powers included this item in his testimony, and my explanation of the necessity for this expenditure is the same as his.

Item 8 is entitled "Hard Surface Plant Roads," and shows expenditures in 1940, 1941 and 1942. In 1940 the plant roads at Stations 8 and 10 will be hard surfaced or black topped, at a cost of $2,855. In 1941 the plant roads at Stations 5, 6 and 7 will be black topped, at a cost of $2,955. In 1942 the plant roads at Stations 2, 3 and 4 will be black topped, at a cost of $3,410. My testimony as to the necessity for those expenditures is the same as that of Mr. Powers.

Items 9 and 10 are now under construction. Authority for the expenditure shown in Item 11 has been granted and the material is under order.

My explanation of book cost of property retired is the same as the explanation given in connection with page 3 of Exhibit 97.

When we install a Transite roof we do not put it on over the iron. We take the iron off section by section, so the building is not open to the elements.

Cross-Examination Interposed by Mr. Slaff.

I stated with respect to Item 3 and page 4 the stations at which the main engine air filters are to be renewed, 625 and with respect to Item 4 I stated at what stations the main engine exhaust mufflers were to be installed.

Direct Examination by Mr. Hedrick Resumed.

Page 6 is entitled "Additional Capital Expenditure for Bunkhouse and Dwellings," and provides for the construction of eight four-room cottages at an expenditure of $33,576, in 1939. I believe Mr. Powers in his testimony dwelt at some length on the necessity of providing dwelling accommodations for certain employees in his operating personnel and also other employees connected with the pipeline and other departments which are situated in the field.

The Natural Gas Pipeline Company has a definite cottage building program under way. This program has been in effect for the past several years and will be extended through the year 1941.

As the stations were originally designed, planned and laid out, each station included a number of dwellings for the employees. Those dwellings are shown on Exhibit 96, under the figure 17. On that Exhibit 96 we show eight cottages. At present there are nine cottages at Station 6; that is, one additional cottage has been constructed at that point.

The original design and layout of the station included accommodations for main and auxiliary operating engineers who would be located at each station. They also provided one house for the pipeline superintendent. Shortly after the start of operations it was found that it was necessary, for the safe operation of this line, to house other personnel than the compressor station personnel at each station. That additional personnel included telephone linemen, meter men, pipeline foremen, truck drivers, welders, division clerks, as well as the repair foremen in the compressor station department and those operators heretofore named.

Shortly after this first cottage building program was undertaken, we started operation under the forty-hour work week. That automatically caused us to employ additional men as operators in the compressor station department and additional auxiliary and main engineers who were eligible for living accommodations at the station site. We were able to bear with this problem for a short time, due to the number of our employees who were then single. These men were housed in bunkhouses and secured accommodations at boarding houses situated on the plant site.

Our building program as now in effect and which will be extended in the future will provide additional living accommodations on the station site for those members of all departments who are eligible for houses and who are not now provided with houses. This item includes the construction of eight four-room cottages in 1939, those cottages to be constructed, one each, at Stations 2, 4 and 7, two at Station 10, three at Station 6, at a cost of $33,576.

It is very necessary in the operation, maintenance
626 and repair of station equipment that operators in the classes named be housed at the station, so that if an emergency occurred at one of the stations or on the pipeline, the employees may be more readily available than if they were in a town five or six or ten miles away or scattered around at places considerably removed from the pipeline.

I might add another point. It is not possible to house all of the employees that work for the pipeline department. The majority of the employees that are working for the pipeline department are what are termed maintenance or laborers. Only the pipeline foremen, superintendents and key men are located in the houses at the station site, where such houses are available for those men. In the event of an emergency arising in the pipeline department, they depend largely on the personnel housed at the central location, that is, the compressor station, for immediate action, and compressor station men as well as pipeline men answer this emergency call. This fact increases the safety factor to an immeasurable degree in so far as operation of the pipeline is concerned, irrespective of the operation of the station.

It has happened quite frequently during the time Natural Gas Pipeline Company and Texoma have been operating that employees were called out at night or while they were off duty for an emergency in maintenance or repairs to the pipeline or compressor stations. It is almost a weekly occurrence in so far as the compressor station department is concerned, and it has also happened in the past on emergencies occurring on the pipeline away from the compressor station.

We have made a practice of interchanging employees between the pipeline department and the compressor department during the past three years. This interchange of employees has the prime motive of training all employees for emergency duty, as well as routine duty, in every department.

The next item is entitled "Construct Six 4 Room Cottages," at a cost of $25,182 in 1940, and represents the cost of two cottages to be constructed at each of Stations 3, 4 and 5.

The item entitled "Convert Three 7 Room Bunk Houses" at a cost of $5,700 in 1940 is the cost of converting a seven room bunk house into a private dwelling house at Stations 2, 5, and 9. Originally, as stated previously, we provided bunk houses and boarding house accommodations for those single employees. The labor turnover on this system has been low. The employees have married and raised families, and the remaining number of single men is very low. The result of this has been that the boarding houses and bunk houses are no longer useful for any appreciable number of employees. In many cases bunk houses were only occupied to the extent of one or two rooms. Inasmuch as we desired to house more employees at the station, and obviously when a single employee was married he could no longer live at the bunk house, and must move to town, we converted bunk houses and boarding houses at six of the stations into private dwellings.

This item, as stated, in the amount of $5,700, is for the
627 conversion of the three remaining boarding houses and bunk houses into private dwellings at those stations stated in the year 1940, and that expenditure will be required and made in that year. There is some possibility that we might construct at least one of these conversions this year. Incidentally, we now have out bids for cottages in 1939.

The year 1941 will complete the cottage construction program. In that year we will construct thirteen 4 room cottages at a cost of $54,561; one cottage at each of Stations 3 and 9; two cottages at Station 7; and three cottages at each of Stations 5, 6 and 8.

Item 2 is entitled "Renew Domestic Water Tanks." The domestic water tank is a galvanized overhead tank, as shown by No. 15 on Exhibit 96. The life of this type of tank is limited, and a number of the tanks now installed have corroded badly on the bottom and sides. This tank is used to provide domestic water for cooking and drinking for the occupants of the cottages. It also supplies the necessary sewage water. One tank, situated at Station 5, has already corroded to the point where renewal has been necessary. A redwood tank was installed at this point as a replacement for the galvanized iron tank. The redwood tank is made of lumber similar to that used in the cooling tower. The condition of the tanks at other stations, as investigated and found, indicates that renewal of these tanks will be necessary in the years 1939 through 1942, if not sooner.

In 1939 we will renew the tanks at Stations 3 and 5. I believe I stated that the tank at Station 5 has already been renewed this year. In 1940 we will renew tanks at Stations 2, 4 and 10; in 1941, at Stations 6 and 7; in 1942 at Stations 8 and 9. These tanks will be renewed at the unit cost of $310 per tank in the years mentioned.

Item 3, entitled "Hard Surface Cottage Roads," is the black topping of the roads servicing the cottages in a manner similar to the roads servicing the plants and described in this exhibit previously. In 1940 we will hard surface or black top the road servicing the cottages at Stations 8 and 10, in the amount of $2,825. In 1941 we will hard surface the road serving the cottages at Stations 5, 6 and 7, at a cost of $3,379. In 1942 we will hard surface the road servicing the cottages at Stations 2, 3 and 4, at a cost of $4,213.

Item 4 provides for the construction of concrete floors in the cottage garage. The original installation in the garages as constructed was of crushed rock or gravel in the cottage area. The plant garages, or those garages situated in the area immediately surrounding the compressor station proper, such as the garage shown by the numeral 5 on Exhibit 96, are constructed with a concrete floor. Concrete floors have been much more satisfactory than rock or gravel floors as used in the employees' garages.

The company regulations require that the garage be kept in a neat and orderly condition, and it is impossible to keep the garages in that condition with crushed rock or gravel floors when the employees drive their cars in covered with mud and knock it off in there, etc. The condition of the garage floors at the present time is not good. They are rutted, and the gravel or crushed rock has a very high
628 percentage of mud intermingled with it.

Item 5 is for hard surfacing tennis courts which have been provided for the employees at several stations. There are seven tennis courts now installed. Since the building of these courts the employees have made frequent use of them. We have frequent petitions sent into the Chicago office for improving these recreational facilities. We have had petitions for lighting the courts, and many petitions for hardsurfacing the courts because it is not possible to keep up a good playing surface at all times with a dirt or improvised court.

The cost of hard surfacing these courts which will be hard surfaced is $1,725 in 1940 at Stations 2, 3 and 4; $1,150 at Stations 5 and 7; and $1,150 for tennis courts located at Stations 9 and 10.

Item 6 is for the construction of additional garage stalls. The construction of garage stalls parallels the construction of additional cottages. Each employee renting a company cottage is entitled to a company garage to house his personal car. In addition, as additional employees are housed at the station there will be other company cars to provide garages for.

Item 7 is for the installation of additional septic tanks and sewage that will be necessary as the housing program progresses. The present septic tanks in use at each station are designed primarily for the original number of cottages located at each station, and as we add cottages at each station additional sewage disposal facilities must be added. Many of the present tanks are now overloaded at those stations where part of the building program has gone forward.

Item 8 is for the improvement of the lighting facilities for the cottage area at all stations, and is now under construction.

Item 9 provides for the construction of additional playground facilities at Station 4. This is also under construction at the present time.

I will explain the situation with reference to tennis courts and playground facilities. No small part of my duties is connected with direction of personnel, and in pursuance of those duties I come upon many problems concerning the welfare of the employees, individually and collectively. The employees desire to secure accommodations at the station, and after securing such accommodations they desire recreational facilities of one kind or another.

Our pipe line, as stated before, traverses a rather sparsely settled area. By that I mean that there are not usually large towns situated close by the station sites. These people engaged in either the operation of the pipeline or the compressor station equipment need recreational facilities of some kind or another. It has been the company's policy to provide such recreational facilities as it felt it could justly do. In my own opinion, I believe such an expenditure as has been made to date has been justified in many ways and has paid big dividends in so
629 far as satisfaction and contentment of the employees are concerned. It is very doubtful in my mind that we could satisfy the employees to the degree that they are satisfied without the provision of such facilities.

To date we have not had any serious labor troubles. I like to believe that the major reason we haven't had such labor trouble is because the management has cooperated to the degree that it has in providing facilities for the employees as requested, and when those employees have shown a real interest in securing such facilities. I believe that the facilities which we provide are really a part of the employees' compensation, although perhaps rather intangible.

Item 10 is for the installation of additional drainage at

Stations 2 and 6. Work requests have been issued for these jobs, and material has been ordered.

My explanation of the retirement at the bottom of page 6 is the same as the explanation of the retirements on page 3 of this exhibit.

(At this point counsel for defendants offered EXHIBIT 97, and it was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed.

Counsel for defendants then presented a document described as "Natural Gas Pipeline Company of America, Operation and Maintenance, Compressor Station Department, Witness, W. H. Davidson." At the direction of the Examiner, the document was marked Exhibit 98 for identification.)

I prepared Exhibit 98.

Line 1 on the first page of this exhibit shows expenditures for operating labor from 1932 to 1954. The expenditures from 1932 to 1938 are the amounts in dollars actually expended for operating labor during those years. That is also true as to lines 1 to 6, inclusive, and lines 8 to 15, inclusive, except that lines 8 to 15 represent items for maintenance. Those are the actual expenditures for the items as listed by lines for the years 1932 to 1938.

The average as shown for the years 1936 to 1938, in the amount of $259,627, is an average of actual expenditures for those years, but it includes the presently prevailing wage scale in only two of those years, that is, 1937 and 1938. In 1939 the volume of gas to be transported by the Natural Gas Pipeline Company will be slightly in excess of those volumes pumped and delivered in 1938, and a slight increase in the cost of operating labor for the years 1939 to 1951, inclusive, provides for that slight increase in gas deliveries.

The difference in cost in 1938 and what we say it will cost in 1939 amounts to approximately $165 per year, per station.

On operating material, which is line 2, the costs for each of the years 1939 to 1951, inclusive, are slightly lower than
the 1936-1938 average and somewhat higher than the
630 1938 average. The cost for the operating materials
that will be necessary in 1939 is $135 less than the average for the years 1936 to 1938, in the amount of $49,042. That difference is so slight that I believe the expenditure could be termed as very nearly the average.

It is my judgment that those amounts to be expended in 1939 will also be expended in the years 1940 to 1951, inclusive. This applies to lines 1 and 2 for operating labor and operating material.

On line 3 I show $300 per year from 1939 to 1952 on account of damages. The company is liable for damages for a number of different things, including damages accruing from waste drainage and loss of cattle due to drinking the fluid from the septic tanks. It is liable to the general public for any condition which might exist because of its operations that may be hazardous. It is liable for fires and explosions that might cause loss on adjoining properties. There have been a number of damage settlements since this portion of the exhibit was prepared. Damages accruing for 1939 are in excess of $560. None of this was for fire or explosion damage. The damage settlements to date in the current year include payment for a number of sheep which were alleged to have been killed at Station 8 from drinking effluent from the septic tank, and also include a settlement, I believe, for a drainage problem.

It is probably true that these small annual figures would not begin to cover or take care of any damage from fire or explosion. However, what I had particularly in mind, although I imagine the record will be a little confusing on that point, were damages from fires occasioned by burning off weeds and grass on the plant site, when I was thinking of fires. We have a large area on the plant site upon which there are no facilities, and we try to keep a large part of the vegetation cut down, but in the fall of the year we burn it off. At several stations there are buildings right up against the property fencing, although we have not experienced any damages from that cause that I recollect. There might be damages from that cause.

We have not made any provision for large items of damage that might occur. As to whether we have any situations existing at the compressor stations which might result in heavy and serious damages to persons or property, we have a situation that was called to our attention last winter, although it has been prevalent for a number of years. That is a situation that exists at each of stations Nos. 4 and 5. Those two stations are situated north of a main traveled highway, adjacent to the station, in about the same position as the highway noted on Exhibit 96. The prevailing winds at those two stations are such that they blow the spray from the cooling tower out over the roadway, and it presents a condition that is hazardous to people driving by the station.

It freezes on the surface of the road and makes it slick. It also, depending upon the atmospheric conditions, creates a fog which obstructs the vision of the driver of the automobile. This matter has been discussed in our office in Chicago, and I have been instructed to place signs at some distance at either side of the station site where this 631 condition exists, and in addition to the signs we place men out there with flags or lanterns, as the case might be, to flag and caution automobile drivers. We do that when it is frozen and also when the fog is real bad. This condition does not prevail continuously. It prevails at certain atmospheric conditions, naturally, and it prevails when the wind is in the north.

Item 4 includes the expenses for myself and other executives of the Chicago office who may have occasion to go out in the field to inspect the compressor stations, and it also includes the expenses of any engineers sent out for special investigation of any particular problem.

Item 5 is the cost of operating fuel for operating the main compressor and auxiliary engines at each compressor station. That yearly amount for the years 1939 to 1951 is somewhat less than the 1936-1938 average. We have used the fuel consumption as in effect the latter part of 1938. In 1938 we effected certain fuel economy in the operation of the main engine equipment, particularly, and we believe and hope that we may continue operation at this low fuel consumption.

Item 6 is for lubricating oils and greases, which are necessary for the operation of all the compressor stations' operating equipment, particularly the main engines and auxiliary engines. The amounts from 1939 on are a little less than the 1936-1938 average.

Items 8 to 15, under the sub-head "Maintenance," are explained in more detail on pages 2 to 8 of Exhibit 98.

Page 9, entitled "Bunk House and Dwellings, Labor and Material," includes the necessary maintenance, labor and material for the bunk house and dwellings for the years 1939 to 1954, inclusive, and includes painting and repairs necessary to the cottages and also the necessary maintenance to the sidewalks, grounds, piping and other appurtenances necessary to the cottages. The amounts shown on this page are not included in the general recapitulation on the first page of Exhibit 98, and will be in addition to that recapitulation.

I used prices as of June 1, 1939, for both labor and materials in figuring the costs of the various items making up this exhibit.

It is my considered judgment, based on my experience and my knowledge of the property of Natural Gas Pipeline Company and the demands upon that equipment in the course of the company's operations, that at prevailing costs of labor and materials as of June 1, 1939, the amounts set forth in Exhibit 98 will be expended by the company in the operation of its business and the maintenance of its property on the respective dates stated in this exhibit.

(At this point counsel for defendants offered EXHIBIT 98 in evidence.)

632 *Cross-Examination Interposed by Mr. Slaff.*

In entering retirement expense on the books of the company, we consult with the accounting department of the company. I have been instructed by the accounting department that such expense is a proper maintenance charge.

Direct Examination by Mr. Hedrick Resumed.

As shown on this exhibit, retirement expense is that expense incurred while making the retirement of any particular item that is retired, that is, labor expense. It is the cost of taking that material out of service, and it is my testimony that that particular expense will be incurred in the years shown in this exhibit. If it is a proper bookkeeping entry as retirement expense, it is my judgment that the expenditure should be included as I have included it here, as a bookkeeping matter.

Cross-Examination Interposed by Mr. Slaff.

Answering your question as to what distinction I make between labor connected with the retirement expense and materials with retirement expense, there are no material items included in retirement expense. They are all labor items. I make the distinction because there is no material used in making the retirement. We retire materials from service in the course of years. I believe, if I am not mistaken, that the retirement of materials is shown in Exhibit 97 under the heading "Salvage and Retirements." I am not familiar with the bookkeeping procedure as to what account the materials retired are charged to.

Cross-Examination Interposed by Mr. Booth.

As to whether I had anything to do with the determination of whether or not the items included in this exhibit are properly to be treated as operating and maintenance expense from an accounting point of view, that the accounting department sets forth a procedure to be followed by all operating departments. We follow that procedure as set forth. Exhibit 98 follows exactly the procedure followed in the everyday run of the business of the company. I received those instructions from the accounting department on the day I started to work for this company, which I believe was in March of 1931. I did not receive any instructions from them in connection with the preparation of this exhibit.

(At this point EXHIBIT 98 was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed. Motion by Commission counsel to strike witness' testimony denied.)

Cross-Examination by Mr. Slaff.

I testified in one other case for Natural Gas Pipeline Company. That case had to do with a lawsuit brought by a farmer residing across the road from our Joliet regulator station. It was a damage suit. (Renewal of motion by Commission counsel to strike Exhibit 98. Company counsel limits purpose of exhibit and Examiner reserved ruling on motion.)

633 R. M. BUSSARD, a witness for defendants, recalled, testified as follows:

Direct Examination by Mr. Morgan.

(July 29, 1939)

When I was testifying on Thursday morning, counsel requested the Examiner to allow my withdrawal from the witness stand in order that I might check the method which I had used in the computation of the composite or average back pressure curves of the several groups of wells located on the areas respectively set forth on Exhibit 90. I have made such a check.

I have considered the matter both personally and with those whom I consulted concerning the engineering problems involved in this study to determine whether or not there was any error in the method of computation. We have concluded that there is no reason to change our method of computation, and I am not bringing in any new change as a part of my testimony.

However, in the course of checking these curves and the charts on which these curves appear in Exhibit 89, we did discover a few errors which I think we should point out at this time.

The mistakes that I want to discuss this morning first are on the fifth page of Exhibit 89, which is the back pressure data chart for well group No. 3-A. In order to locate the points of error, I will speak of the horizontal scale in terms of the cycles from the left hand edge of the sheet. Starting at the left hand edge and moving to the right to the end of the second cycle on the horizontal scale, we find the figure "5" and then above it a "1" and a "0". The little figure above the "5" appears to be "10." It should be "1.0." The drafting room was in error there.

To locate the next correction I wish to make on this sheet, progress to the right to the end of the succeeding cycle on the scale, at which we find the figure "1.00." The drafting room made an error there, and that figure should be "10."

I would like to say that the mistakes on the chart have not affected our calculations. In fact, they did not enter into our calculations at all.

Another mistake which I find is on page 8 of Exhibit 89, which is the page for well group No. 5. The charting of the composite line on this sheet is in error at the pressure factor point of 15,000. The composite line is located at 1.3 as drawn on the chart for the value 15,000, whereas it should be located at a Q quantity of 1.03. Again we have an error that occurred in the drafting room at the time the chart was constructed. The error does not occur in our calculations. We have prepared a revised page for this particular group, if you desire it.

634 (At this point the corrected sheet for Group No. 5, at the direction of the Examiner, was marked Exhibit

99. EXHIBIT 99 was offered and received in evidence without objection.)

The document which is marked Exhibit 99 is the corrected chart on well group No. 5 appearing in page 8 of Exhibit 89.

While I was on the stand the Examiner asked some questions concerning some symbols appearing on page 1 of Exhibit 89. I am prepared to explain those symbols.

When I was explaining this section of page 1 of Exhibit 89 called "Calculation of Back Pressures at the Sand," I was asked for the meaning of the symbol P_2^2. P_2 is a symbol which was obtained from the Bureau of Mines publication RI 2929, and, as defined in that publication on page 2, is the absolute pressure at the wellhead in pounds per square inch. Therefore, the symbol P_2^2 on page 1 of Exhibit 89 is P_2 multiplied by itself, or the square of the wellhead absolute pressure.

RI 2929 is not the same as Monograph No. 7. It happens that the Bureau of Mines made their first report concerning their back pressure work in two reports of investigation, RI 2929 and RI 2930. Both are dated May, 1929.

All of the other symbols in that portion of page 1, which is called "Calculation of Back Pressures at the Sand," are defined in this report of investigation 2929 on page 2, and the symbols are also defined in Monograph No. 7 on page 141.

I here read into the record an extract from RI 2929, at page 2, showing the definitions of the various terms:

"Method of Computing Pressures at the Sand in a Gas Well.

Nomenclature.

"The following nomenclature has been used in the formulas and in explaining the methods of computing pressures at the sand in a gas well from volume and pressure observations at the wellhead:

P_2=Absolute pressure at the well head, pounds per square inch.

P_1=Absolute pressure at the well head plus the pressure drop due to friction, pounds per square inch.

P_s=Absolute pressure at the sand, pounds per square inch. (Absolute pressure at the well head, plus the pressure drop due to friction, plus the pressure due to the weight of column of gas.)

P_f=Absolute formation or "shut-in" pressure in the sand, pounds per square inch (absolute pressure at the well head when shut in, plus the pressure due to the weight of the column of gas).

635 Q=Rate of flow, cubic feet per 24 hours, at 14.4 pounds per square inch and 60 degrees F., assuming an average flowing temperature of 80 degrees F. in the producing "string" of casing or tubing. (It is here assumed that 80 degrees F. represents an average temperature in the producing string, and the actual variation from this assumed condition will not create any considerable error in the computation of pressures.)

d=Internal diameter of the producing string, inches.

G=Specific gravity of gas (air=1).

L=Length of pipe, feet.

R=Combined factor selected from Weymouth's formula 4 for flow of gas through pipe=square root of $P_1^2 - P_2^2$ (See P. 18).

e=Base of Napierian logarithms=2.71828.

F=Correction factor for density due to pressure variation in the flowing column of gas (see p. 21)."

Questions by the Examiner.

I think I can give a general statement about the formula in the upper lefthand portion of page 1 of Exhibit 89 which I decided not to use.

These expressions to which the Examiner refers have to do with the calculations for the determination of the weight of the moving column of gas and also have to do with the calculations for the determination of the pressure effect of friction in the string of pipe. I left the impression from my answers that I did not make these corrections and that if I had made the corrections the expressions called for would have resulted in very minor errors. I did not express myself very clearly on that point. What I intended to say was that I did not go through the long calculations. I did not do all of the mathematical work involved in solving the formulae, and the reason I did not do that was because there had been developed certain tables which, in effect, solve these formulae and permit us to materially reduce the work involved in determining the correction for the weight of a column of gas and the correction for the friction effect.

At the time this formula on page 1 of Exhibit 89 was made, only R. I. 2929 was in publication, and our production engineers who made that form for our regular use made it in that particular manner following the symbols and formulae indicated in R. I. 2929. At a later date these tables that facilitate our work were developed, and at the time Monograph No. 7 was published in late 1935, I think, the tables were incorporated in the monograph and are shown therein. In other words, we have been using a calculation sheet such as this since late in 1931, when this particular formula on page 1 of Exhibit 89 was prepared by one of our production engineers.

636 R. I. 2930 was also in publication but had no particular bearing on this. The No. 2929 relates to computing the pressure at the sand in a gas well and is called Part 1. R. I. 2930 is a fundamental relation for gauging gas well capacities, and is Part 2 of the publication then made.

As to what I mean when I say "correction for the weight of the column of gas," perhaps if I say why we do that it will explain. We desire to determine the pressure conditions at the bottom of the well, the bottom hole condition, as we call it, but our gauges used in recording the test data are located at the head of the well up at the ground surface. So to get from the ground surface record to the bottom hole pressure, we must add to the ground surface record the weight of the column of gas. I think there was nothing other than just dead weight that I was taking into consideration; there was nothing like inertia.

Direct Examination by Mr. Morgan.

When I was withdrawn from the stand, counsel was about to ask me some questions concerning one of the charts shown in Exhibit 91, having to do with the rock pressures of wells belonging to Texoma in the several groups shown on Exhibit 90 and with the projected weighted average pressures in those respective groups of wells.

Counsel refers to the rock pressure curves dealing with wells in Group 1 and rock pressure curves dealing with the wells in Group 8, pointing out that my estimated future curve for the wells in Group 1 approaches the righthand side of the chart at a point which I have taken as 25 pounds well head gauge at the end of 1954, and that the same line on the page of the chart representing Group 8 has a different course; that the curve in Group 1 is represented by a line that is comparatively straight when compared with the course of the curve shown in Group 8, where the line takes more the course of the righthand half of a rainbow. I am asked to explain how I account for the difference in the behaviors of the pressures as I conceive them to be in those two groups during the period from January 1, 1939, to the end of 1954.

The difference in appearance of the two lines comes about primarily from the fact that the weighted average rock pressure in Group 1, as of January 1, 1939, was materially lower than the weighted average rock pressure in Group 8 as of January 1st, 1939. In other words, the weighted average pressure of the area to which I have referred as Group 1, as of January 1, 1939, was approximately at 270 pounds, and the weighted average pressure prevailing in Group 8 as of the same date, January 1, 1939, was approximately 384 pounds.

I am asked to explain the circumstance that the pressures in an area where they have already been reduced to 270 pounds on January 1, 1939, will so decline as to be equalized with the pressures in Group 8, which I found to be 384 pounds on January 1, 1939, by the end of 1954, and to explain what it is that will cause those lines to take such different courses over that same period of time.

The lines necessarily take the different courses be-
637 cause of the difference in total rock pressure decline
that will occur in the respective groups. Group 1 is close to an area quite highly developed and from which there has been a considerable quantity of production. Necessarily, the weighted average pressure in Group 1 has been materially affected by this production and has declined materially to this 270 pounds average that the chart shows. On the other hand, the area represented by Group 8 has had very little development in it. The company has very few wells there, and, in fact, the other companies have very few wells there.

In the future there will be more wells, and as there are more wells drilled in area No. 8, necessarily the rock pressure is going to decline more rapidly because of the greater quantity of gas that is being taken out of it. This general trend of distribution of production is not confined to Group 8 particularly, but it is something that is going to happen in the field as a whole. We are going to see increasing amounts of drilling in areas not now highly developed. As the production spreads it is going to have its effect upon the rock pressure and we are going to see an accelerated decline, because there will be not only the general drainage effect throughout the field, but there will be this increased concentration of production, or, rather, it is a spread of production which increases the tendency of the area to decline in pressure.

It is our opinion that as this production spreads, the field begins to become more and more uniform as to pressure conditions, and eventually, when the gas is taken from the field, there has to result a uniform pressure condition.

As the production spreads throughout the field and reduces the rock pressure in what are now the higher pressure areas, there necessarily results a lesser drainage into that low pressure area and into Group 1. Over a period of time it must occur that the repressuring effect into Group 1 will be less than it has been.

Our schedule contemplates drilling one more well in Group 1 and an additional nine wells in Group 8 on Texoma's property. There will be a number of other wells drilled in that area by owners of other leases, because that is a comparatively undeveloped area. When these additional wells are drilled on Texoma's property and additional wells are drilled on the property of others, the pressure decline in that area will be accelerated as compared with what it has been in the past. Obviously, the pressure decline is going to increase, because the decline is dependent on the drainage from the area and the quantity of production from the area, and the more you produce the more the pressure decline will increase. That pressure will go down at a faster rate as compared with what it has declined during the past years.

In our study as to the future capital requirements of
Texoma we have used these weighted average rock
638 pressures indicated by the estimated future line in conjunction
with our back pressure chart work, in that, knowing the rock pressure from time to time, we can refer to the various group back pressure charts and determine the quantity of open flow that will exist at the corresponding date in the several groups.

The open flow for the wells to be drilled in a particular area in a particular year is determined by taking the rock pressure in that particular year and group and going to the composite back pressure line for the group and determining the open flow from this composite line and then, of course, assigning that open flow to the wells in the group in the year.

By the use of the two curves, the curves shown on Exhibit 91 and on Exhibit 89, we are able to ascertain how long the present wells of Texoma would produce a sufficient quantity of gas to meet the requirements of the Texoma portion of the pipeline outlet. By using the rock pressure data in conjunction with the back pressure data we can tell how much a well in the particular group would produce, and I speak of an average well in the group, and thereby build up the total production for the company and relate that to Texoma's portion of the market demand of Natural Gas Pipeline Company.

As to the other uses which I have made of the facts and principles developed by these curves and the calculations which these curves represent in the economic study in which I have been engaged, the rock pressure data and the back pressure data permit us to make a number of rather important determinations by finding the quantity of gas to be produced in a given year. In a given year we can determine how much gas the booster stations in that particular area are going to handle, and thereby with the rock pressure conditions and the volumes to be handled we know how much horsepower we have to have. We know when we have to put the horsepower in. We know where we have to put the horsepower.

Also we can determine the size of the gathering line that has to be laid from the new well to the existing gathering system. We can determine such things as we need in Mr. G. M. Davidson's estimate of the gasoline plant revenue in that we can find the quantity of gas to be produced in Moore County in a given year and in the other counties, and inasmuch as there is a difference in the gasoline recovery, we are thereby enabled to get a more accurate picture of the quantity of gasoline recovery.

As to whether I made use of the same principles in determining the future drilling requirements of Texoma in order to have available this full quota of the pipeline's market outlet during the latter period of the project's life, I will say that inasmuch as we can by use of the rock pressure and back pressure data determine the quantity that the wells can produce, we could determine what well drilling would be required to meet Texoma's share of the full market requirements of the pipeline company.

As we proceeded from year to year in our study, we always saw to it that the production did not exceed 25% of the open flow, because there is a law in the State of Texas that prohibits production in excess of 25% of the daily open flow quantity of the well. That is a statutory requirement, or limitation.

I have already stated that in determining the num-
639 ber of wells to be drilled I collaborated with Mr. J. G.
Dickinson, the general superintendent of production of Texoma Natural Gas Company. In this study I have undertaken to determine, in consultation with Mr. Dickinson and others, the number of wells that Texoma will drill in the future, the time when it will drill those wells, and the location of those wells as they are drilled.

The future well drilling program and the location of the wells has been a matter of collaboration, and Mr. Dickinson and I have worked quite closely on that together. In distributing these wells from year to year and in the various groups, we have to take into consideration the particular area, and we have to consider the contractual obligations of our leaseholds and of our consolidation agreements. We have also to consider the need for protection against outside drainage and against drainage by others close by the areas in which we have leaseholds. It is also necessary that we take into consideration the management's direction that we so distribute the cost of drilling and the other costs contingent upon the drilling throughout the future of the company that there may be no undue burden imposed from year to year upon the revenues of the company, and, necessarily, we also want to avoid deferring drilling until just that very day in which we get into a shortage of open flow and then have to try to drill our wells all at once in order to maintain our market position. The result of this work that Mr. Dickinson and I have prepared together is a well drilling program.

These considerations of lease requirements and drainage protection, and the policy of the company in distributing the burden of its drilling program over the whole life of the field instead of deferring it until the production must be had in order to meet the immediate situation—or, to state it otherwise, conducting its drilling operations on a hand to mouth basis—govern the spread of the drilling throughout the years, and not the total number of wells to be drilled. We have arrived at the total number of wells to be drilled by the application of the engineering production principles which are illustrated by Exhibits 89 and 91, together with the cost of doing the drilling and the revenues that can be obtained therefrom. I have prepared a tabulation setting out the number of wells to be drilled and the schedule of the drilling.

(At this point counsel for defendants presented a document described as "Texoma Natural Gas Company; Future Wells, Gathering System and Booster Station Program; Witness, R. M. Bussard." At the direction of the Examiner, the document was marked Exhibit 100 for identification.)

That tabulation is the first sheet in Exhibit 100. Along the lefthand side of this page are the words "Group No. 1," and below the figure "1" some other figures; then, "Total Carson-Gray" and some other figures, and then "Total Moore" and "Grand Total." Confining ourselves to that portion of the page, which is approximately the upper half of the page, those numbers refer to the Texoma well groups that we have used in our Exhibits 89, 90 and 91. When I speak of Group No. 1 on this exhibit, I am talking about that pink area over in the western part of Gray County, as shown on Exhibit 90.

640 The figures in the column headed "1938" are the number of wells owned by Texoma in the several well groups as of December 31, 1938. With one exception, those wells were all then completed and either connected with our pipeline or about to be connected with the pipeline. As of the date given, these wells were in production.

To illustrate the figures in the column headed "1939," I will take the first figure in the column which is the number "2." That is set opposite Group No. 2, so that there is an indication that we intend to drill two wells in this particular well group in 1939; in fact, those wells may have been drilled at this time. I am not just clear in my memory as to that. I take the first of January, 1939, as the dividing point, for reasons already reflected by the record.

The second figure "2" is to the effect that there will be two wells drilled by Texoma in Group 3-A in the year 1939. Next we find that there will be one well drilled in Group 3-B. Moving on down, the figure "5" opposite "Total Carson-Gray" simply indicates that there will be a total of five wells drilled in the Carson-Gray County area during 1939 by Texoma.

We move on down to the figure "2" opposite Group No. 7, which means that there will be two wells drilled by Texoma in Group No. 7 in 1939. Similarly, the numbers below relate to the number of wells that will be drilled in each one of the groups during 1939. Then we come to the number

"17" opposite "Total Moore," and that means that there will be a total of 17 wells drilled by Texoma in 1939 in Moore County.

Finally we see the number "22," and there we have the gross number of wells to be added to production during 1939 by Texoma.

If I went through it in detail, my explanation of the figures under the captions of 1940, 1941, 1942, and so on across the page, through the year 1951, would be the same.

In effect we have assigned Group 6 to Carson County; but it is actually in Hutchinson County. It is a terminology on our part. We just refer to the area east of Fritch station as being Carson-Gray County, and this will apply also to Group 5. Group 5's boundary lines are up in Hutchinson County a little ways.

The totals show that there are 22 wells to be drilled in 1939, 20 to be added in 1940, 20 in 1941 and 20 each year on through the year 1944. That indicates the total number of wells to be drilled each year during the period 1939 to 1951, inclusive. Just one well will be drilled in 1951, 9 in 1950, and 12 in 1949. We have determined that there will be a total of 215 wells added to Texoma's production after the first of 1939, which, including the wells already drilled and on production, will make a total of 350 wells.

The lower half of this same page of Exhibit 100 is an accumulation in that the starting figure at the end of 1938 has added to it the subsequent yearly drilling, and this
641 sheet simply shows how many wells are on hand at the beginning of each year, and finally totals 350 wells.

In getting the gas into the pipeline from the 215 wells which are to be drilled after January 1, 1939, we will have to lay lateral lines in order to connect those wells to the existing system, and when the rock pressure becomes inadequate to cause the gas to flow to Fritch and arrive there at an adequate pressure, we will have to install booster stations in the field.

We have made a study as to the lateral line and booster station requirements in connection with these 215 wells that Texoma will add to its production after January 1, 1939, and the second sheet of Exhibit 100 contains a summary of the lateral line construction required by the well drilling program.

The first column, of course, speaks for itself and shows the years during which the wells will be drilled, as shown in the schedule on the first sheet of this exhibit about which

I have been testifying. The second column shows the same figures as those reflected on the first sheet as to the number of wells to be drilled.

There are five columns immediately to the right of this second column under the general caption "Miles and Size of Line." The figures at the head of the first four columns in this section are the diameters of the lines that we anticipate we will have to lay to connect the future well drilling to the existing gathering system.

Taking the column headed "Four-inch" and going downward, we find the total amount of four-inch pipeline that would have to be laid each year in the future to connect the future well drilling to this system. Similarly, under the columns headed "Six-inch," "Eight-inch," and "Ten-inch," we find the annual quantities of additional gathering lines to be required. The final column in this particular section is headed "Total" and is the gross mileage added by the capital expenditure of Texoma for well lines each year that the drilling program continues, and down below is a summation of the total amount of mileage laid throughout the drilling period.

We expect to lay 106.61 miles of four-inch gathering line from the first of 1939 to the end of 1951. The symbol "R" means that we are taking one section of line out by retirement. This is because we had to make a shift on account of our booster station development and the line was not needed any longer. The total column carries only the net for the year.

We expect to lay 67.8 miles of six-inch line in the future well drilling activities, 17.89 miles of eight-inch line, and 1.68 miles of ten-inch line.

Coming back to that letter "R" at the bottom of the column under the four-inch, I called attention to the fact
that opposite the year 1951, in the column headed
642 "Total," we show the net amount of pipe added to
the system during the year. I did not make a specific reference to reclaim. I just wanted to call attention to the fact that the reclaim was not included in the mileage shown on this sheet.

When I speak of reclaim, I mean we take the line up out of the ground and stock the pipe. It is not necessarily retired from the plant account as long as the pipe is taken in stock. It would go out of plant in service and into materials and supplies if the company retained ownership.

To the right of the group about which I have been testifying there are some figures under the general caption "Change Connections." "Change Connections" relates to some work in addition to the laying of the well lines and the connecting of these lines to the existing system.

As we go into the future and construct booster stations, we will have to make some changes in the lines from time to time, and we will be disconnecting a four-inch line from, let us say, a ten-inch line and reconnecting that four-inch line to another line, possibly a line which has been laid for the purpose of an intake line into a booster station. These quantities in this particular section called "Change Connections" simply mean that we will cut loose so many connections of a certain size in a certain year and reconnect the line to another part of the gathering system.

The figures as to the quantities of pipe taken up and retired from plant account and put in stock or used somewhere else will all be developed through another witness.

Over on the right hand side of sheet No. 2 is a double column of figures under the general caption "Well Connections, Meter and Regulator Setting, Etc.," with the subheadings of "Four-inch" and "Six-inch." The future well drilling will not produce wells of uniform size. We commonly use a four-inch meter piping and six-inch meter piping, depending upon the size of the well. These two columns to which I have referred simply indicate the size of meter piping that will be required for a certain number of wells in the different years, and they are just an indication to the man who has to make the cost estimate that he should provide in his cost estimate for these numbers of the various sizes shown.

We build gathering lines of different diameters out to different wells in the field. The diameter of the gathering line depends upon the quantity of gas the line has to carry, the length the line will be, and the pressure conditions under which that line will operate. The variations of those three factors are the determinations of the diameter of the lines shown in our gathering system construction program.

We have made a very careful study of the quantities and sizes of lines that will be required to connect these 215 wells with the gathering system. In fact, that is one of the uses of the correlation of the rock pressure data and the back pressure charts.

In the pages immediately following sheet No. 2 of
643 this exhibit we have shown the details of the gathering system construction for each of the several years of the drilling program. Pages numbered 1, 2, 3, 4, 5, 6, 7, and on to 12, inclusive, are devoted to such details. These detail sheets are self-explanatory and can be readily correlated with sheet No. 2. They are simply the details of each of the years and the totals for each year as brought forth on sheet No. 2 of this exhibit in the recap.

On page 1 of these detail sheets there is a note which reads "This assumes the Pythian property is purchased." The word "purchased" is somewhat erroneous, and should be "acquired." By this particular note I mean to refer to a proposition the company has up with the Phillips Petroleum Company, whereby Texoma will trade a well and some lease for a well and lease of the Phillips. The name of this particular lease and well that we expect to get from the Phillips is called the Pythian.

Another element in that trade is the gathering line between the well and our existing 24 inch trunk. That happens to be some 3.8 miles, as indicated on this sheet, and included in our negotiations with the Phillips is the item of purchasing that quantity of gathering line. That exchange of properties has been actually effected. The transfer was made after these figures were compiled, but it is now effective and that qualification is no longer necessary.

Questions by the Examiner.

The Phillips well was already connected to our lines because we have an agreement with the Phillips Petroleum Company for the exchange of natural gas. This was a line through which they were bringing gas to us under their exchange agreement. One of the wells that Phillips Petroleum Company used to deliver gas to us under their exchange agreement has now been acquired by Texoma. In other words, they were swapping gas for a while and now they have swapped wells.

Direct Examination Resumed by Mr. Morgan.

The results of our analysis and study of the booster station requirements are set forth starting with page 13 of the exhibit. Page 13 is a summary of the booster station program. The upper third of the page relates to the number of stations that will be installed in Moore County and to the number of stations that will be installed in the other counties in which Texoma produces.

The figures might be explained by taking the year 1946 and finding the figure 19 opposite Moore County. As of January 1, 1946, we will have booster station power installed at 19 different points in Moore County, according to our calculations and estimates. They will be installed in 1945. We chose the first of the year as a very definite breaking point, for simplicity of presentation.

The figure to the right of the figure "19" is "30" and that figure "30" indicates that as of January 1, 1947, there will be booster station power installed at 30 points in Moore County. This means a total of 30 points, of which 11 will have been constructed during the preceding year. By this I mean that there will be 11 different additional booster station locations brought into the
644 Texoma field property during 1946. When I say location, I mean the buildings, engines and all of the piping and everything else that goes with that station, a completed, ready-to-operate station.

Questions by the Examiner.

These are not what would be called centrally located booster stations. They are more in the nature of decentralized stations. I believe Mr. Brown said there was a possibility of adopting a decentralized program, and this particular program we have gotten up here is more in the nature of a decentralized program. There are some instances where there are stations which have on their intake only one well; but they would be few in number. The number of wells on the intake varies from station to station.

Direct Examination by Mr. Morgan.

On page 13, moving out to the last column under the year 1954 are the numbers 30, 30 and 60. The first 30 means that there are 30 booster stations installed in Moore County as of the first of 1954. The second 30 means that there are 30 booster stations in Carson, Gray and Hutchinson Counties. The total installation as of the first of 1954 will be 60 stations. There will be 60 locations at which booster stations will be built as of that date, and there will be 60 booster stations handling the production of 350 wells as of the first of January, 1954.

There is another group of figures under the caption "Number Units in Use, Moore County, Carson, Gray and Hutchinson Counties," and so on, immediately below the group of figures about which I have just been testifying. The figures under the caption "Number of Units in Use" tell us how many engines are in use in the several stations that have been built as of January 1st of the years under which the numbers appear. For illustration, under the caption "Carson, Gray and Hutchinson Counties," for the year 1939 there is a total of one. That means one booster station engine is in use now. It is in that group of Carson, Gray and Hutchinson Counties. By the end of that year or the beginning of 1940, we will not have to add any engines in Carson, Gray and Hutchinson Counties, and that one unit which is in use as of the first of 1939 is still the only unit in use as of the first of 1940. We will have to put two more engines into operation during the year 1940; and I arrive at that figure by seeing that under the year 1941, as of January 1st, we will have three engines in use.

There are no booster stations provided for in Moore County, or engines provided for use in booster stations in Moore County, prior to 1946. That difference in requirements is a reflection of the pressure conditions existing in the various areas. The pressures in Moore County are sufficiently high that it is not until during 1945 that our study shows any need to install any booster station horse power in Moore County. We are providing for these booster stations and this booster station investment as it is required during the future history of the project.

There is a third group of figures opposite the lines under the caption "Horse Power in Use" on that same page 645 13 of Exhibit 100. We have just been talking about the number of units in use, and inasmuch as the size of the engine that we contemplate is a 40 horse power engine, we multiply the number of units by 40 horse power per unit to represent the horse power in use at the dates shown, and that simply refers to the aggregate horse power of the engines which are shown in the group of figures immediately above it.

As of the first of 1954 our study shows that Moore County will require 126 units, containing a total of 5,040 horse power. Our studies further show that for the same date, and for Carson, Gray and Hutchinson Counties, we will have to have 81 units in service. These 81 units amount to 3,240 horse power.

However, Texoma as a whole will have to have 207 units in service as of the first of 1954, accumulating to a total horse power of 8,280. These will be gas engine driven compressor engines.

We have spoken of compressor engines in the field by using the term "Booster Stations" in order that we may have a differentiation between the power that we have to install in the field and the power that is installed at the Fritch station, which we ordinarily call a compressor station in our words. It is the same thing, but geographically located at different points. We use the two terms for convenience in conversation.

Questions by the Examiner.

As to what will be the lowest possible intake pressure for these booster stations, I will say that these engines will operate to a very low intake pressure; but the lower the intake pressure the less the capacity of the engine to handle the compressed gas. If we were operating under one intake and the intake pressure diminishes, one way we could make an adjustment to operate would be by changing the gas compressor cylinder size. Those cylinders are removable.

Direct Examination Resumed by Mr. Morgan.

Pages 14 and 15 of this exhibit give details relating to the location of the various booster stations and to the number of engines in use at each station at the beginning of each year. There is nothing about that detail and correlating it with page 13 that needs explanation.

(At this point counsel for defendants offered EXHIBIT 100 in evidence, and it was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed. Motion by Commission Counsel to strike witness' testimony in connection with Exhibit 100 as deals with anything beyond a reasonably immediate future denied.)

I have prepared a map which shows the location of the 251 wells drilled and to be drilled after January 1, 1939, and the location of the booster stations which are to be put into operation after the first of January, 1939.

(At this point counsel for defendants presented a map described as "Texoma Natural Gas Company, Panhandle Gas Fild of Texas, Gas Wells, Gathering System and Field Booster Stations." At the direction of the Examiner, the map was marked Exhibit 101 for identification.)

Exhibit 101 was prepared under my direction, and
646 shows the gas field property of Texoma Natural Gas
Company. This property is divided by color between property existing in the field on January 1, 1939, and the property to be constructed thereafter. I will start with the top of the legend and go down.

The first symbol in the legend is a black circle opposite the words "Present wells," and that means that the several black circles show the location of the wells that Texoma had on January 1, 1939. Wherever that circle appears on this map, at that location Texoma had on production a well as of January 1, 1939.

The next symbol in the legend is a solid black line, and this solid black line shows the location of Texoma's gathering system in the Panhandle field as of January 1, 1939.

The next symbol in the legend is a solid green line, and this solid green line shows the location of Texoma's telephone system in the field as of January 1, 1939.

The next symbol is a black triangle, and this black triangle shows the location of the booster station which Texoma owned as of January 1, 1939. There was only one at that time, and it is located in Section 102, Block 5, I. & G. N. Survey, Carson County. That station is used for a series of wells as it is located there. As I recall the construction of the intake line to that station, it pumps out of the lateral line, and therefore all of these wells, including the one on the direct line, are feeding into that station.

The sold red line in the legend relates to the gathering system, that is, to the pipelines which Texoma will need to construct after the first of January, 1939, in order to connect with the wells which will come into production after that date and the general gathering system of the company.

The broken green line represents the telephone system construction which Texoma will have to make in the field after the first of January, 1939.

The solid red circle represents future wells to complete development, and the various points on the map on which these red dots are located give the location of future wells to be drilled by the Texoma Company.

I see that I have missed the red triangle, which relates to the location of booster stations to be installed by Texoma in the field after January 1st, 1939, and those are the 60 points that we spoke about in a previous exhibit, and they stretch throughout the field.

The remainder of the legend is a solid black line with diagonal red lines running through it, and a solid red line with diagonal red lines running through it; and these relate to the parts of the gathering system which we think Texoma will have to take because no longer usable. A diagonal red line across the black line indicates that
647 it is a piece of property existing on the first of the year 1939 and will probably become no longer usable and will be reclaimed. Where we find a solid red line with a diagonal red line across it, we mean to indicate that some construction after January 1, 1939, will later on prove to be no longer usable as originally built and will be reclaimed.

Exhibit 101 shows the geographic distribution of the wells already drilled, the gathering lines already in existence, and the booster stations in existence as of January 1, 1939, and the wells, gathering lines and booster stations as shown in Exhibit 100. All 350 wells are located on this map, and all the pipeline mileage and all the booster stations are shown here. Within the usual drafting limits, they are accurately located on that map.

(At this point counsel for defendants offered in evidence EXHIBIT 101, and it was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed.)

(Counsel for defendants offered in evidence EXHIBIT 91, and it was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed.)

Cross-Examination by Mr. Slaff.

I am requested to take any well or any year in the future and explain how I use Exhibit 89 to determine the open flow of a well to be drilled in one of the groups in any future year, showing the step by step method.

I am going to take the rock pressure decline map on Group 8 as an example of the determination of the rock pressure as of January 1, 1946. I wish to state that my actual calculations were based upon a calculation I have discussed in the testimony, but I shall use the chart for illustrative purposes.

On January 1, 1946, the rock pressure decline map of Group 8 shows that there was 292 pounds gauge well head pressure. If I might, I would like to forego the calculation on the weight of the column of gas and assume that 292 pounds was the formation pressure absolute as of that date. The symbol will be P_f. Having determined a formation absolute pressure of 292 pounds, I next go to the back pressure data chart for Well Group 8 in Exhibit 89.

In this chart relating to Group 8 the left hand scale relates to the pressure factor. The pressure factor is $P_f^2 - P_s^2$. In my illustration I will use 292 pounds as P_f and 13 pounds as P_s. The square of 292 is 85,264. The square of 13 is 169. The difference of the squares is 85,095.

We now find on the vertical scale the point 85 and proceed from that point to the right until it intersects with the composite back pressure line. We then proceed downward to the horizontal scale, and as I read the chart, we reach the horizontal scale at a value of 4,300,000
648 cubic feet per 24 hours, and, if I have not made a mathematical mistake or a chart mistake, I have given you the answer as to the method that we use in correlating rock pressure and the back pressure test data.

That is illustrative of the method. Actually we went through a formula because of the mass of information we had to prepare.

Questions by the Examiner.

To my mind, the significance of the words "back pressure" is twofold. It is to distinguish from the ordinary Pitot tube open flow method, where the gas leaves the well and blows to the air without there being anything to hold the pressure back against the sand, except the weight of the column of gas/ but in that particular test procedure illustrated on page 1 of Exhibit 89 we call that a back pressure test, or the Bureau of Mines did, because the gas is producing into the ordinary string of pipe, the ordinary lateral line, and the pressure is being made in that line and being held back against the face of the sand rather than just blowing open to the air. The recorded data as to the well head pressures are the back pressures existing at the time the tests are recorded.

649 J. G. DICKINSON, a witness for defendants, recalled, testified as follows:

Direct Examination by Mr. Morgan.

(July 31, 1939.)

I have heretofore stated that my position with Texoma Natural Gas Company is that of general superintendent of production. My duties as general superintendent of production include supervision of the accounting department where charts from Texoma's meters are figured, gas royalty computations are made, and royalty checks are prepared. We have the job orders covering investment work done for Texoma, and a general set of Texoma's books is kept in the Amarillo office.

My duties also include supervision of the land and lease department. In this department we handle the taking of leases, the preparation of consolidation agreement contracts, and the handling of complaints and legal work.

I also supervise the geological department. In this department we keep maps, sub-surface data, sub-surface maps, analyses of well samples. The geologists recommends the location of wells and determine the depth at which casing is to be set. They locate the gas pays when the wells are drilled in. They keep statistical information and make reserve estimates.

The production department comes under my supervision. This department makes locations of wells in the field. They haul in rig material and casing. They furnish fuel for the drilling. They recommend the depth at which the first string of casing is set. They supervise the cementing of casing. They survey the hole to determine if it is straight. They watch samples and assist the geologist in the locating of the depth of the gas pay. They drill in and log gas pays. They inspect charts of well meters. They test wells and blow wells to remove water and cavings. They supervise the clean-out work.

In addition to these activities I act as agent for Texoma in Texas. I represent Texoma in dealing with the regulatory bodies and in matters of public relations. I am familiar, of course, with the contractual obligations of Texoma in the matter of its lease obligations.

I spoke of supervising the accounting that is done in Amarillo. That accounting, of course, is done under the general direction of Mr. Campbell, the secretary, who prescribes the system of accounting which I see is followed out in the keeping of accounts in Amarillo.

I am sure that Texoma has not a sufficient number of wells already drilled on its properties to meet its requirements for the future. We have plenty of open flow at this time to meet our requirements; but as the rock pressure declines the open flow of the wells will decline, and at a
greater rate. The open flow will decline to a point
650 where we will not be able to produce enough gas from
the presently existing wells to meet Texoma's outlets.
In order to meet that situation we propose to drill enough wells to provide the requirements of Texoma's market; and, after giving thorough consideration to the problem, we have decided to do it in a uniform and orderly manner.

I have been requested to tell something about the history of the company's policy with reference to eastern Gray and Wheeler counties, and explain why Texoma would sell gas from those wells instead of connecting those wells into the pipeline system, in the light of the circumstance that Texoma will probably need more gas for its own purposes.

In the beginning Texoma had a considerable amount of acreage in eastern Gray and western Wheeler Counties, and we contemplated building a line into this area, not only to take care of Texoma's wells that we acquired in this area, but also to take care of any future drilling we might do. At about the time we were ready to start work on this line in Wheeler County, it was decided to postpone construction of it. We had sufficient gas on the west side to get us started, and we decided to defer building the line until a later date.

Early in the history of Texoma's production, the State of Texas became very lax in the administration of conservation laws, and stripping operations were finally permitted, which had a very serious effect on the pressures in the area of central Gray County and also in Wheeler County. This production of gas in these two areas brought the pressures down to such an extent that we began to examine the problem rather critically to see whether we should build into the area at all. We finally decided that the building of a line into eastern Gray County and Wheeler County would not prolong the life of this project at all; that we would be able to get sufficient gas from the western area up to the time the field was exhausted; and exhaustion of the field was dependent not only on our own withdrawals but the withdrawals of others; so we finally determined that we would not build a line into eastern Gray and Wheeler Counties.

This resulted in our surrendering most of the acreage that we had in those areas in order to avoid the payment of rentals, taxes and other costs of carriage. With respect to building a line into the area to serve the wells which we had, we decided against this proposition because the cost of a line to take care of these wells would be more than twice the cost of drilling wells in other areas to provide the same amount of open flow that was available in these areas. The rock pressures in central Gray County and in Wheeler County are now at a point where we could not deliver gas into our pipe line under present pressures.

Exhibit 101 does not extend far enough east to show the wells owned by Texoma in the Lefors area of eastern Gray County and the wells belonging to Texoma in Wheeler County.

Questions by the Examiner.

My attention has been directed to an isolated well with a
proposed booster station, and a short distance from
651 that, an isolated well and a proposed well, and I am
requested to state what happens to those wells.

At such time as those wells decline to a point that they will not feed into the line against prevailing pressures, we will have to have booster stations. At the present time those wells are connected to Cities Service Company by an exchange agreement which is cancellable on 60 days' notice. The wells are so located that we can take them into our lines at any time we find it necessary. We have six wells that feed into Cities Service lines on exchange agreements.

Direct Examination by Mr. Morgan.

By that I mean that we are delivering our gas from wells which are near their lines and they are delivering us an equivalent quantity of gas from some wells of theirs which are near our lines. By that means we have been able to effect an economy by being able to avoid the building of gathering lines. Under these exchange agreements we simply deliver them a quantity of gas and they redeliver to us a similar quantity. No money changes hands; it is simply an exchange of gas.

The six wells connected to Cities Service are Purvis No. 1; C. C. Yowell; two J. J. Crutchfield wells, one of which is in Section 37, Block 4, I&GN Survey, Carson County, and I believe the other is in Section 38; Gulf No. 1-G, in Section 21, Block 5, which is several miles from our line; and Burnett D-1-G, in Section 34, Block 5, I&GN Survey, Carson County.

We also have some wells in eastern Carson County and western Gray County where we are now delivering to Phillips. We are doing that to avoid installing booster equipment right at this time. They are down in the low pressure area in western Gray County. Phillips is producing from wells in the same area into a line and can receive this gas at these low pressures where we could not do it at all. We would have had to build a booster station before this time in order to get that gas into our system against prevailing pressures. In return for that Phillips is delivering gas to us close to Fritch and they are delivering some of it from northern Moore County into our gathering lines.

By means of that exchange we have been able to keep our capital investment down, but up to this time I do not believe the amounts would be material. We would probably have had to build one or two small units in order to get this gas into our system. All of the wells east of a point in Section 25, Block 4, I&GN Survey, Carson County, are now delivering gas to Phillips. That is a temporary arrangement and does not result in decreasing the quantity of gas that goes into our system that would otherwise come from those wells by any quantity at all.

Except the Coltexo and Lone Star wells, which are not shown on this map, this covers all of the wells under exchange agreements.

652 The Phillips exchange is on a quality basis, and not on a well basis. It involves 18 million cubic feet daily.

On Exhibit 17 the wells in the Lefors area which are connected to Coltexo's pipeline are those wells located generally directly north of the non-productive area that is shown in white on Exhibit 17. There are now six wells connected to Coltexo, and the total open flow of these wells is approximately 15 million cubic feet. The rock pressures range from 146 pounds to 200 pounds.

These wells could not be economically produced into our pipe line system. We would have to build a compressor station and build a line over to the terminus of our line in Western Gray County. The terminus of our line is about five miles directly south of the town of Pampa, and it is about 15 miles from that terminus over to these Lefors wells. We would have to build a compressor station to pump the gas and build a gathering line to the wells. We would not be able to produce the gas into our line in the absence of a compressor station. It would not require an enlargement of any part of the additional line to take delivery into the system.

There are seven Texoma wells in Wheeler County connected to the Lone Star. I will name those wells and give their locations.

Gordon No. 1-T and No. 2-T are located in Section 91, Block 17. The rock pressure of both of those wells is 216 pounds. The open flow of No. 1 is 26,000,000, and the open flow of No. 2 is 21,000,000.

Hicks No. 1 is located in Section 53, Block 17, H&GN Survey, Wheeler County. It is in the center of the northeast quarter of the southwest quarter. Its rock pressure is 281 pounds, and its open flow is seven million.

Morgan No. 1 and No. 2 are located in Section 93, Block 17, H&GN Survey, Wheeler County. Morgan No. 1 has a rock pressure of 231 pounds and an open flow of 11,600,000. No. 2 has a rock pressure of 219 pounds and an open flow of four million.

Sewell No. 1 and No. 2 are located in Section 1, Block 24, H&GN Survey, Wheeler County. No. 1 has a rock pressure of 209 pounds and an open flow of 18,400,000. No. 2 has a rock pressure of 207 pounds and an open flow of 10,000,000. The total open flow of these seven wells in Wheeler County is 98,893,000. The average open flow of the wells is 14,000,000 per well.

Comparing the costs of building a gathering line over to Lefors and Wheeler County wells and drilling wells in the Carson-Gray area in the vicinity of our pipeline, as con-

templated in the program as portrayed on Exhibit 101, it
would be more economical to drill wells in the western
653 part of the field. In fact, it would cost about half as
much, or less than half as much, as building, for example, a ten-inch line into Wheeler County. The distance from the terminus of our pipe line over to those Wheeler County wells is about 29 or 30 miles.

Those wells in Wheeler County would not by means of their own pressure deliver gas into our Fritch station, and in order to get the gas from that Wheeler area we would have the same situation as that in the Lefors area, namely, that of building field compressor booster station equipment in order to deliver it in.

When I said that it would cost more than twice as much to build a pipeline and make the other investments necessary to deliver gas from these wells into our system, I was talking about drilling the same number of wells over in the Carson area.

The six wells in the Lefors area have a total of about 15 million cubic feet of gas daily. The situation in Lefors is such that all the wells over there have an open flow equal to about one well in the other part of the field, and what I said would apply to all of the wells in both the Lefors area and Wheeler County with respect to open flow; that is, we could drill the same open flow in the west part of the field at less than half the cost of building a line to connect this open flow in central Gray County and Wheeler County, because in one well we would get as much production as we have in all six of those in Lefors. Those are the six wells Mr. Kesinger testified were due to be plugged and abandoned in the next two or three years, and I think that is what will happen to them. They are in the same vicinity and in the same situation as the six wells we have already abandoned.

I said a while ago that it would not add any time at all to the life of this project had we connected these wells or had we developed the Wheeler and eastern Gray County leases and connected them into our pipeline system. By that I meant that the life of the Panhandle field and the life of Texoma's operations is going to be determined by the rate of withdrawals from all sources. Thus, we are able to get the gas we need in the western part of the field and the building of a line into the eastern part of the field won't be any help in prolonging the life of Texoma's pipeline, because the western part of the field is going to last longer than the eastern part. The pressures in Wheeler County are quite low as compared to those in the western part of the field. This is reflected very graphically by Exhibit 17.

I understand about the limitations which Mr. Bussard referred to when he said he computed the future available open flow to Texoma on a basis of taking a maximum of 25% of the open flow daily from each of its wells. That is a legal requirement in Texas, that wells will not be produced in excess of 25% of their open flow.

It would not be safe for Texoma to so handle its drilling program as that it had barely four times as much as the
daily outlet available from its wells, for this reason:
654 Texoma is required to shut some of its wells out in
order to prepare them for rock pressure tests. Some of the wells are out of the line for clean-out operations. Some of the wells are shut out for blowing. The gathering lines freeze up in winter time, which causes the shut-out of some of the wells. In considering the number of wells and 25% of their open flow, Mr. Bussard has taken a theoretical viewpoint of it. It does not consider the practical angle. He is talking about the maximum that could be accomplished if conditions were at all times ideal.

Something has been said about some of the wells being off the line for blowing, and I am requested to state why it is necessary to have some of these wells off the line for that purpose and to describe that operation of blowing these wells.

Mr. Galloup, our production field superintendent, inspects charts on Texoma's wells, and when he detects characteristics in the charts which he can identify, he goes out, or sends some of his men out, to blow these wells. This blowing is to take the water out of the well or to blow out cavings, and the process is to shut off the side gate where the well feeds into the gathering line and then open up the top gate and let the well vent itself to the atmospheric pressure. That blows the water or other foreign matter that has gotten into the well out through the top of the well.

Questions by the Examiner.

The charts referred to are recording charts. They record pressure and differential. The pressure pin makes a mark around the 24 hour chart and then the differential that measures the difference in pressure across the orifice also records another line around the chart. These are meter charts.

Differential is the difference in pressures. On the upstream side of the orifice the pressure will be higher than on the downstream side of the orifice, and knowing the size of the hole and the difference in the pressures we calculate the volume of gas passing.

Direct Examination by Mr. Morgan.

I have spoken of water as one of the things which we blow out, which Mr. Galloup went into at some length, and I am now requested to explain how this other matter gets into the well or formation and why it is necessary to blow it out of there.

The gas as it comes into the hole is saturated with water and the release of this pressure tends to let some of this water drop out. This water runs down the sides of the well bore and causes the lime to flake up and causes the shale to cave. It becomes mud and falls into the bottom of the hole. This foreign matter accumulates and begins to have some effect on the producing characteristic of the well. It restricts the flow, or in some cases it causes the differential pin to be very erratic and to have a choppy motion when it should be smooth. We have to blow the wells to get this out in time, because if we leave it there too 655 long we have a clean-out job, and it has been my observation that some of this debris that is blown out may come from the producing horizon itself rather than off the walls of the well bore. Some of this water may begin to drop out back where this pressure begins to decline away from the well bore. For example, we have one well in Carson County that last week we had to blow twice because of the debris in the well, and it took about an hour each time to clear it out. The debris seemed to continue to come after an ordinary period of blowing, which usually does not exceed thirty minutes.

The operation of blowing the well will not be as effective as a means of cleaning out the water and debris from the bottom of the hole in the future as it is at the present time. As the pressure declines and the open flow declines, we reach a point where it will be very difficult to get this water and foreign matter out. We will then have to install tubing.

Mr. Bussard has testified that the schedule of wells to be drilled by Texoma in the future totals 215 wells, including those that have been drilled since the first of January, 1939. I assisted him in working out that schedule. My judgment is that that estimate is all right from a theoretical standpoint, but it does not take into account the practical considerations. It is based on the assumption that the theoretical flow characteristics of Texoma's wells are going to remain the same over their entire life, and that in turn infers that there will be no change in the reservoir conditions.

We are pretty certain that that is not going to happen. I had Mr. Kuhne make back pressure tests of 30 of Texoma's wells that were tested in 1932 and 1933 again in 1938 and 1939. We find that on those thirty wells the open flow which we would expect at a 100 pound pressure has declined 50% between the tests in 1932 and 1933 and the tests in 1938 and 1939. So we have rather definite evidence that there are going to be changes in that reservoir and also in the flow characteristics of the wells. I think from a theoretical angle Mr. Bussard's study is good; but, in my opinion, it is too conservative with respect to the matter of drilling.

(Motion by Commission Counsel to strike above testimony and objection to any future testimony dealing with a period beyond the reasonably immediate future denied and overruled. Statement by Company Counsel that the company is entitled to all future additions as part of present rate base.)

I have stated that there would be changes in the open flow of these wells indicated by these back pressure curves. The character of the changes will be such that it will tend to lower the open flow for the reason that the open flow is affected adversely by the mechanical clogging of the pore spaces, by the intrusion of water, and by changes of that character in the producing horizon. Those are the two fundamentals.

In concurring with the schedule of 215 wells to be drilled on Texoma's property as indicated by Mr. Bussard, I am concurring only to the extent that it is the indicated number if the potential could be expected to stand up to the indicated level which he has developed through his back pressure curves and pressure decline curves. I mean by that that I think more wells will be required than indicated by Mr. Bussard's study.

In my statement that my observations between 1932 and 1938 showed a 50% loss from what we expected, I meant that the back pressure curves taken first indicated certain open flows at 100 pounds pressure and the second tests gave a result which was 50% less than the result we obtained the first time at 100 pounds pressure, indicating to me that the reservoir had plugged up to such an extent that it brought about this change in the result. It could not have been drained. In the event of drainage the pressure factor would have been taken care of in the curve. A change in the reservoir condition is the only thing that could explain it.

Direct Examination by Mr. Morgan.

What I am saying is that there were two back pressure estimates made, one back in 1932 and 1933 and another in this year and the latter portion of last year, and the open flow indicated on the second test was 50% lower than on the first test.

Cross-Examination Interposed by Mr. Slaff.

If the indicated open flow was ten million in 1932, 50% of that indicated open flow in 1938 would be five million. If the open flow were five million in 1938, 50% more would be seven and one-half million in 1932 instead of ten million.

Direct Examination by Mr. Morgan.

In order that the matter may be clarified, I will explain that the first back pressure tests were taken in 1932 and 1933, and the second tests were taken in 1938 and 1939. The results of the tests indicated that the open flow which would be expected at 100 pounds pressure was 50% less in 1938 and 1939 than was indicated in 1932 and 1933. That indicates to me that there is a change in the reservoir conditions to the extent that the pore spaces are obstructed so as to prevent the flow of gas into the hole in the manner which was indicated by the first tests.

Questions by the Examiner.

What I meant in my reply to Mr. Slaff's inquiry was that if the first figures were ten, then 50% less than that would be five. If the figures were five, 50% more would be seven and one-half. If I had an open flow of ten in 1932, I looked at the chart and figured that we would have seven and one-half million in 1938, and we actually came out at half of seven and one-half million. We read our back pressure curves to find our prediction for 1938, and the result in 1938 was half of our prediction. The rock pressure both times was above 100. We were reading on the chart at the 100 pound rock pressure mark trying to determine the open flows at 100 pounds by our back pressure chart method, and the result of the readings in 1938 and 1939 were 50% less than they were in 1932 and 1933. We constructed two back pressure charts on different dates 657 and got two different theoretical results.

Direct Examination by Mr. Morgan.

This was due to changes in that five year period between the times they were taken. That was not in all of Texoma's wells but just in 30 wells that we had data on in 1932 and 1933, and it indicates that in those 30 wells these mechanical difficulties we have been talking about here had intervened to thwart what would have been the open flow without further obstruction. We know that the open flows of Texoma's wells decline more in a period of time than is indicated by back pressure tests taken immediately after well drilling. We have that practical check on it.

We have drilled 18 wells so far this year, and will drill a total of 22 wells during this year.

The changes in the reservoir conditions due to water and shale are the things that change open flows as indicated by the back pressure curves. Those are the two fundamental conditions and are interchangeable.

My impression is that if the number of wells around Texoma's wells be increased and thus reduce the drainage area, it would not have any material effect on the flow characteristics of the wells except to reduce the pressure in the area more rapidly than that indicated.

Although we have a potential in our present wells adequate to meet our present market requirements, we have already drilled some wells and will drill four more this year. We have made a considerable study to determine our drilling program, and for a number of reasons we have decided to adopt a uniform and orderly program. Some of these wells that we are drilling now are required by consolidation agreements. Some wells which Texoma is now producing are assigned large acreage assignments and are producing at a higher percentage of open flow than we think is desirable.

The drilling of wells now gives us an opportunity to anticipate and meet implied lease obligations with respect to the development of large leases. These implied obligations accumulate, and if we don't take care of them as we go along we get some complaints from the lessors. We can handle a uniform and orderly drilling program with a minimum investment in rigs and derricks and casing, and at less contract hauling expense.

We can handle a uniform and orderly drilling program with our present trained personnel. Mr. Galloup and Mr. Peterson have both had many years of experience in different fields, and we think it is desirable to handle a drilling program which our own men can take care of.

658 The producing of wells at a moderate rate of open flow, at a moderate percentage of their open flow capacity, results in less mechanical clogging of the pore spaces. There is less danger of water encroachment at moderate rates of flow. There is less formation of condensate in the well bore at moderate rates of flow. We obtain a better spacing pattern of our wells, and hence a more uniform drop in pressure as far as Texoma's operations are concerned, and this in turn will delay to some extent the installation of particular booster units. I believe that covers the reasons why we want to drill in a uniform manner.

That is the settled policy of the company and has been the settled policy of the company during a period of years. We have anticipated the drilling of wells in a uniform manner. To some extent in the early formation of our consolidation agreements we delayed drilling in order to bring leases into consolidation. For example, we are prorating on the basis of open flow and acreage, and we attempted to show the land owner that it was to his advantage from a royalty standpoint to put as many acres under the wells as he could. That situation helped us in the formation of those consolidation agreements, and during that period we held up on some of our drilling in order to offer them the first well as an inducement to make these agreements.

I have seen the schedule of wells as outlined by Mr. Bussard, showing the nmber of wells to be drilled in each of the years from 1939 to 1951 inclusive, and I have taken that schedule of wells and developed the cost of drilling those wells. The costs of drilling these 215 wells drilled and to be drilled after January 1, 1939, were based on actual experience in drilling in the areas which we contemplated developing. A well in Moore County we estimate would cost $22,014, whereas a well in Carson and Gray Counties we estimate will cost $17,702.

Those two amounts take into account the difference in depth to which the wells have to be drilled and the difference in the formation characteristics, which will have the effect of making drilling in Moore County more difficult than it is in Carson County and also more costly. On the average, the wells in Monroe County would be 500 feet deeper than those in Carson and Gray.

Costs as of June 1, 1939, were used as the basis of our calculations in fixing the cost of those wells. It was necessary for us to figure out the number of wells that would be drilled in Moore County each year and the number of wells that would be drilled in Carson and Gray Counties each year. We have done that and have prepared an exhibit which sets up the schedule of costs of drilling these additional 215 wells.

(At this point counsel for defendants presented a document entitled "Texoma Natural Gas Company. Additional Capital Expenditures and Operation and Maintenance, Production Department. Witness, J. G. Dickinson." At the direction of the Examiner, the document was marked Exhibit 102 for identification.)

Page 1 of this exhibit is a summary of the additional capital expenditures of the production department of Texoma Natural Gas Company.

659 On the lefthand side of the sheet is a tabulation of the captions under which these capital expenditures will be made, and the years under which these expenditures come are shown at the top of the sheet and across to the right. For example, well drilling in 1939 requires an expenditure of $418,720. This amount in 1940 becomes $414,408, and so on.

Sheet No. 1 is supported by detailed sheets. Page No. 2 illustrates the information as to the number of wells in Carson and Gray and Moore Counties, and the cost in each county group, which supports the figure of $418,720 on the first line. Then the amount in each year is shown on page 2. The totals correspond with the amounts in the first line on page 1.

Turning to page 2, it will be noted that in 1939 we have five wells in Carson and Gray and fifteen wells in Moore. Further over on the same line we have $88,510 as the cost of the wells in Carson and Gray and $330,210 as the cost of the wells in Moore. The $88,510 is obtained by multiplying $17,702, which is the cost of one well, by five, the number of wells to be drilled in Carson and Gray Counties. In like manner the $330,210, which represents the cost of drilling in Moore County, is arrived at by multiplying $22,014, the cost of a single well, by fifteen, which is the number of wells to be drilled in that county during 1939.

That accounts for twenty of the 22 wells which I stated were scheduled to be drilled this year. The other two wells were commenced in 1938 but were completed in 1939, and were charged as of the time they were commenced.

The same explanation applies on down that column of figures on the upper half of page 2, making a total of 67 wells yet to be drilled in Carson and Gray Counties and 146 wells yet to be drilled in Moore County, at a total cost of $4,400,078.

That capital cost includes the drilling of the well and the casing, the master gate and the Christmas tree. The Christmas tree is represented by the fittings at the top of the well and includes the gate valves for the control of the well, which is a series of valves above ground. It includes the master gate and a gate on top of that for blowing and a side gate off the well and small valves to release pressures so that the big valve may be operated. These sums do not include the cost of installing a meter, the base on which that meter is installed, the meter connection, or things of that kind.

Going back to page 1 of the exhibit, a second line is shown called "Well Liners," and an aggregate sum of $18,450 to be expended during the years 1940 to 1947 inclusive. We usually finish our wells in eight-inch casing. As a well is drilled in we frequently encounter shale interspersed in the lime formation. This shale when the water condensate gets on it falls into the hole, and we have found

that by the installation of liners we can prevent some of this difficulty. These liners consist of six-inch pipe and are usually about 600 feet long. They extend from the bottom or near the bottom of the hole up into the eight-
660 inch casing. These liners are slotted in each joint by an acetylene torch and long slots are cut in every joint of pipe so that we let the gas in but keep the formation back to a very large degree.

The thought might occur that the cavings would come in and shut off the slots. This was true when we bored holes instead of slots. The caving would get in there and plug that hole and seal it off, but usually in a slot there will be a little place where gas can get through and that gas would keep running that piece of caving up and down until it finally wore it out and blew it out. They are rather effective in keeping the well hole clean. That is similar to what is known as a sand point in a water well.

These liners we anticipate installing in 41 wells. These are wells that have already been drilled by Texoma but which do not have liners at the present time. We have liners in about 40 wells. There are some wells that we need to run liners in, but in some of them which we have drilled we encountered our open flow in too much volume to be able to run a liner. It is necessary to wait until that open flow declines in order to be able to get a liner down the hole.

In some wells the well appeared to be in such a condition after drilling in that we wouldn't need a liner, but we found later that we have a lot of trouble with cavings in these wells so that we will need to install liners. These liners will necessarily be installed at such time as we move in tools to clean out, because we will need the drilling machinery and the equipment in order to put the liner in the hole, and as we reach these wells for cleaning out in which no liners have been installed, it is our purpose and determination to install liners in those wells which we think need it.

It costs $450 to provide and install a liner in a well. We have $3600 for liners in 1940, which is a total of eight liners. We have seven in 1941, seven in 1942 and 1943 and 1944, two in 1945, two in 1946, and one in 1947, making a total of 41. I think that is the rate at which liners will be installed in these 41 wells. It is a program that I have developed in connection with my consultation with Mr. Galloup. It is quite likely that some of these liners will have to be installed at an earlier date than scheduled here. These are the latest dates to which we felt we could delay this work.

The details as to installing these liners are shown on page 2. That shows the number in Carson and the number in Moore and the total number for each of the years from 1940 to 1947 inclusive, and the total cost. In my judgment, that sum of money will be expended in the installation of liners in Texoma's wells not later than the times indicated in this part of the exhibit, the second half of page 2.

Cross-Examination Interposed by Mr. Slaff.

I mean that in my judgment that sum of money will be expended and that the number of liners will be installed.

In making this estimate we based our prices on prices
661 as of June 1, 1939. In my judgment, that could well
be a reasonable figure in 1947; but I have not formulated any judgment as to what prices will be or could be in 1947.

Direct Examination by Mr. Morgan.

On page 1 there is a third line, labeled "Well Tubing," in which we show a schedule of $11,585 for the year 1941, $17,313 for 1942, and varying amounts on through the year 1953. Texoma's wells are completed usually with eight-inch casing. As the rock pressure declines and as the open flow declines it will be more and more difficult to blow the water and cavings out of the hole. To alleviate this condition the common practice in gas well operation is to install tubing, which is usually two inches in diameter. This tubing extends from the top of the hole to about the center of the gas pay, and the installation of the tubing increases the velocity of the gas and permits the blowing of the water and debris from the hole at low pressures and with less gas loss than if it were blown out of the big hole, and it has the additional ability to get the water and cavings out in a great many cases where you could not do it without the tubing.

We have estimated that approximately 58% of Texoma's wells will require tubing. We hope that some of the areas will not become affected with water and that in some wells we will be able with our liners to keep down the debris to the extent that we may not have to have tubing in them.

It is possible that we have been too conservative in this estimate. We may have to have tubing in more wells. This represents our judgment as to the minimum amount of tubing which Texoma will be required to install. This tubing estimate is carried on the upper half of page 3 of this exhibit, and like the cost of drilling, the cost of installing tubing is controlled by the location for its installation. For example, in Carson County the installation of tubing cost is $1,094 per well, whereas a tubing installation in Moore County would cost $1,223.

That tubing stays in the well once it is installed. It is left in there and the well continues to produce from the casing, but when we want to blow the well we shut the valve on the casing and open the valve on the tubing, and it blows through the tubing. It is just a small metal pipe. It looks just the same as two-inch line pipe.

I have set out the number of wells which in my judgment will be tubed and the time they will be tubed in the Carson-Gray area and in the Moore area, separately, on the upper portion of page 3. It shows a total of 90 wells in Carson and Gray Counties and 114 wells in Moore County, a total of 204 wells out of the 350 wells that we estimate Texoma will eventually acquire. This makes a total of $237,882 that we will be required to expend for tubing.

The totals shown on page 1 under the first solid black line across the page and opposite the words "Total Gas Wells Expenditure" are simply the sums of the amounts to be spent for well drilling, well liners, and well tubing for each of the years 1939 to 1953, inclusive.

662 The next line is designated "Drilling and Cleanout Tools." There are three items, one of $25,780 for 1940, one of $28,270 for 1945, and one of $22,770 in 1951. I will explain the use to which we put cleanout tools and the necessity for having those tools from the standpoint of Texoma's production department.

As I have described previously, we are troubled to a considerable degree with the caving formation in the well bore. Sometimes this caving can be removed by blowing the wells, but oftentimes it forms that solid bridge and cannot be removed, or else it accumulates to such a degree in the bottom of the hole that it cuts off some of the gas pay.

We now have one cleanout machine which we expect to remodel. This is an old-style machine and in its present condition is hard to move around. We expect to utilize it and make it more portable. We anticipate the rebuilding of one of our rigs at a cost of $3,100. The rebuilding of that machine we anticipate to cost $2,000. In addition to that, we intend in 1940 to purchase a new cleanout machine, which will cost $5,500. We will purchase two strings of tools at a cost of $7,590 each, a total of $15,180, making a total for the year of $25,780.

It will be necessary to buy a new cleanout machine and these additional strings of tools, even though we are going to overhaul the one we have now, because we expect to use one machine in Moore County and one in Carson County. There is quite a long distance between these two counties, and the moving of one machine from one locality to the other would cost a good deal of money, and we anticipate that one machine won't take care of our needs during this period. When these wells get in a situation where they must be cleaned out, it is necessary to clean them out before they are restored to normal production.

It is my judgment that this is a minimum requirement for cleanout and drilling machinery and equipment that Texoma will have to provide not later than the year 1940. In figuring the cost of that equipment we have used the cost as of June 1, 1939.

We anticipate that this equipment will take care of our needs until 1945, when it will be necessary to buy an additional machine. We calculate that by this time we will have worn out or lost the two strings of tools which we bought in 1940, and that we will be required to purchase a string of tools for the new machine and two strings of tools to replace the old tools, at a total cost of $28,270.

We estimate then that in 1951 we will have worn out or lost the three strings of tools we had in 1945, and it will be necessary to replace them at a cost of $22,770, making a total of $76,820. These costs were figured on the same basis.

When I speak of tools being worn out or lost, I refer to losing them in the hole and not being able to fish them out. It happens quite often if a line breaks, a drilling line breaks, and you are not able to get hold of it with fishing equipment or in fishing you mash out the end of the tools so you can't get over them, you usually wind up by
663 leaving them in the hole. Oftentimes, in a case like that we drill by them. We start a new hole and drill alongside them, but we still leave the tools in the hole. We can bring the well back on production but we cannot recover the tools under those circumstances.

If we do not lose the tools by 1945 it will not be necessary to make this replacement, except that we will wear out the drilling lines. We will have worn out the drilling line and the sand line and some of the surface equipment that goes with a string of tools. A large part of the string of tools will have to be replaced by that time whether we lose them or not.

This losing of tools in a well is a frequent occurrence. We have it occur in our drilling operations right along. Our contractors have that kind of trouble. We have lost tools in the well and been unable to recover them in two instances.

This detail of clean-out tools is set out on the bottom of page 3.

The detail of the next item of expenditure, "Houses, Garages and Warehouses," is found on page 4. In general, it represents the housing and garage facilities which we need to install to take care of our personnel during the years. As we drill additional wells we will require additional well operators and additional car and truck facilities. Our field housing facilities are located at Dumas in Moore County and at Kingsmill in Carson County.

In the year 1940 we have scheduled houses in the amount of $10,103 in the Dumas camp. In Dumas we anticipate the erection of one 4-room and one 5-room house in 1940. At the present time there are two houses at this locality. Both of them are occupied by employees of the gathering system. The two production department operators should have houses during this year. One of them lives in Amarillo and is driving to the field every day, and one of them lives in a little shack in Dumas. We also expect to build a 5-room house at Kingsmill during 1940, and to provide garage facilities as indicated in the estimate here. The total expenditure for that year will be $17,521. The items for garages at Dumas and Kingsmill are to take care of the company's cars assigned to these operators and also to take care of their personal cars.

The properties of Texoma in Moore County are pretty widely scattered. They cover an area of about 30 miles across. It is not possible for our production men to get around to attend to their duties without having a car, and that is why the company maintains company cars and puts them at their disposal in connection with the discharge of their duties. Also, from the standpoint of the man working out in the field and his own personal convenience, it is necessary for him to maintain a car out there because otherwise his wife could not get to town very often. It is about 50 or 60 miles to the town of Amarillo, which is the principal town in that area.

The additional houses in 1942 and 1943, and on later,
664 1947, 1948 and 1951, are necessary as we increase our
operating personnel, and that is based on the personnel required to operate the property; taking into account the number of wells which we expect to drill. The present personnel cannot continue to look after the wells as they are increased in number from year to year, and this will require the putting on of additional men and the providing of additional housing facilities.

It is my judgment that for these houses and garages which are set forth on page 4 in detail, the amounts shown on that page and in the recap on page 1, in the line designated "Houses, Garages and Warehouses," will necessarily and actually be expended by Texoma not later than the dates indicated.

I do not in my studies bring in an estimate of the cost of maintaining and keeping up these houses because that has been handled by Mr. R. T. Powers, who is taking care of the maintenance and repair of all houses in the Texas Panhandle. It is a part of his duty to keep up all the houses, not only at the Fritch plant but the houses assigned to production and pipe line employees out over the field, and those figures are shown in the studies that Mr. Powers brought here when he was on the stand, including Exhibit 94.

A warehouse is a place where we store materials that we need out in the field from time to time. The purpose of a warehouse is to keep the material in condition and protect it against the weather and against loss or theft.

The garages are divided into two classifications, one for company trucks and cars, and the other for personal cars of employees who are entitled to cottage facilities. The need for the garages for the company trucks and cars is the same as the need for a warehouse. We need those garages to protect the equipment from exposure to weather and to protect it against loss through theft.

A reason for the company's policy in making available to some of its employees cottage facilities and facilities for protecting their personal cars is that we need employees at those locations. In having them near the scene of their work we save automobile expense and we save time. It is a matter of importance that these men be available in the area as much of the time as possible in order to take care of any emergency that might happen and be able to handle better the job that they do.

Another reason for providing houses is the competitive situation. Other gas companies operating in the field and other oil companies make a practice of furnishing houses for their men. The carbon black companies do it, also the oil pipeline and the oil producing companies, and if we are to retain the quality of men which we need in our operations we have to meet those competitive conditions.

I think I can best explain to what extent other gas pipeline companies, oil companies, refineries and carbon black industries provide housing facilities for their men out 665 in the field and around their plants by some illustrations. For instance, the Phillips Petroleum Company has a complete town right north of the town of Borger which is called Phillips, and was previously known as Whittenburg. There are several hundred houses in this camp. They have also provided playgrounds and tennis courts and various other facilities which are for the purpose of making their employees satisfied to live in that location. They have provided schools, and have actually built and operate a high school, that is, a public school that advances a pupil on through high school grades in that vicinity.

It is a proper and necessary thing in my judgment that those things be provided in that particular territory because if an employee lives in town he has available a great many facilities that are not available in the field, and since it is unreasonable to do the driving that is necessary for employees working in the field who live in town, we have in some measure to provide some facilities of that character in the field. I think without doubt that the employees consider the availability of a house and garage is a part of the compensation they get for working for the company. We know when we go after them to hire them for a job that that is one of the questions they ask us—is there a house available. To my mind it is just a necessary part of our operation.

Questions by the Examiner:

We charge a nominal rent for the houses. This rent just about covers the repair and depreciation of the property.

For those who do not have houses we do not have a subsistence allowance. The men for whom we do not furnish houses are as a rule temporary employees and we pay them by the hour. When we get through with the particular job we have for them to do we let them go. They are usually local people who live in the nearby town, and in a great many cases they are farmers who work part of the time on the farm and part of the time for us.

Direct Examination by Mr. Morgan.

Such revenues as are received from the rental of these cottages are included in the general revenues which have been brought in here by Mr. Woodford, for instance.

All the items on page 1 have been covered except the item of leaseholds. The $2,800 scheduled for leaseholds during 1939 has already been expended. It was made to acquire leases to be added to consolidation agreements that are already in effect. It was money we had to expend in effecting the consolidation agreement.

We are not through with consolidations. We will have additional work of this kind, and in our operating budget for the land and lease department we include money under the item of "Miscellaneous" to carry on the work of consolidation.

A considerable part of the expense of securing consolidations is expense incurred in getting the consent of the
royalty owners under Texoma's wells to allow addi-
666 tional acreage to be put under those wells for produc-
tion. Some of the item may be expended for the acquisition of an additional small tract or two; but that is not included in the investment item.

It is necessary to spend money in order to get the parties to join in a consolidation agreement because the royalty owner under a well will not get any more royalty if additional acreage is added than he is getting now. The compensation is to get him to permit additional acreage to be assigned to his well, and the money for royalty to be paid out of the production of the well that is on his own land. In other words, so far as he is concerned, he is satisfied with the situation without any consolidation if the well has already been drilled. A consolidation agreement affects him a little adversely because as we add additional acreage we further distribute the royalty payments that are made based on acreage and open flow, and he thinks when we approach him with a consolidation agreement that it is something desirable from our viewpoint, and since he does not care anything about it his attitude usually is that he will do it if there is some money in it for him.

The figures on page 6 of Exhibit 102 show the amounts for operation and maintenance of the Amarillo office and the Amarillo land and lease department.

The lefthand side shows the classification of the items of expense, and across the page at the top are shown the years that these items of expense were incurred or will be incurred. From 1932 to 1938, inclusive, are actual operating figures. The next column shows the average from 1936 to 1938. That is the period during which the pipe line has been loaded and that is the reason those years were selected. Additional years are shown from 1939 to 1954, inclusive, and the figures in those years are estimated figures based on past expenditures, consideration being given to the fact that some additional expense will be incurred as Texoma does additional drilling.

We will have increased expense for clerical salaries, for instance, because we will have more charts to calculate and more incidental expense to handle in connection with the operation and maintenance of additional wells. This, of course, occasions increased office supplies and stationery and printing, and as we add additional help to calculate the charts and handle this work we will require additional office space, which will run our rentals up.

This is not just an offhand guess or estimate. We have carefully worked this estimate out and taken into consideration the past expense and tried to construct as accurately as we could the conditions with which we would be confronted as we added additional wells.

This applies to the other items as well as to clerical salaries, office supplies and the items which I have mentioned specifically, except that we have eliminated the item of miscellaneous expense and tried to classify it and include it in the other items.

It is my judgment, after due consideration and care-
667 ful study, that Texoma will incur these expenses for
operation and maintenance in our operations over the period of time covered by this exhibit.

I have not broken the expense of the Amarillo office and land and lease department down into any detail. I have broken the production department estimate down in detail, and that is found on page 6-A. The details of this are subsequent to this page. There is no page 5 in this exhibit. We misnumbered it and called it page 6 and the other page 6-A.

We have classified well operation and maintenance under two main headings, one, well operation, and the other, well maintenance. Under well operation we show labor, material, car and truck, damages, traveling expense, gas royalties, and miscellaneous. Under well maintenance we show labor, material and car and truck. The details for the item of labor are shown on page 7, in which we have shown a unit cost per well. By unit cost I mean the cost on which our estimate is based by actual experience. In 1939 we estimate some increase in that cost due to adding additional wells and due to additional expenditures because of the aging of the properties. The unit cost per well for labor for the years is shown in the first column to the right of the column showing the years, and this means an average for each year.

The $72.50 represents the current unit cost for labor in the operation of our wells. It will be different for the other years because the property is aging, and it has been our experience that as wells grow older they require more attention, and we have attempted to allow for that in this estimate.

Since 1932 there has been a change in the working hours and in the wage scale of those engaged in the operation of the wells, and, therefore, in order to arrive at this unit cost, we picked last year where we had the latest year reflecting present hours of labor and labor scales, and the average cost per well in 1938 for labor was $72.50; for material, $9; for truck and car, $15.50; and for traveling expense, $3.50.

The righthand column represents the number of wells in operation connected to our gathering system in 1938, and for each year after that we have the number of wells that will be in operation. The advance from $72.50 to $73.04 per well for operating labor in 1939 is due to an allowance for increased attention to Texoma's wells as they become older. The same is true in materials, car and truck, and traveling expense. We have added seven cents per well for increased material; twelve cents per well for car and truck expense; and about three cents for traveling expense. Those estimates are based on actual experience. That is what happens as wells get older. We have to allow for increosed attention as the property ages.

The same thing is true of maintenance. These unit costs
increase as the property becomes older, and it requires
additional labor and materials and car and truck expense
for maintenance. Last year the average net mainte-
668 nance cost for labor was $4.50 per well; for materials,
$9 per well; for car and truck expense, $1 per well.
In 1939 we have stepped up the cost three cents per well
for labor, seven cents for materials, and one cent for trucks.

The figures shown on page 6-A for labor, materials, and car and truck reflect the amounts calculated on a per well basis that are shown on page 7, with the exception that under "Well Maintenance" the item of cleanout expense is shown under "Materials," and under "Car and Truck," and under "Labor" expense. This cleanout expense is also represented in detail on page 8. We estimate that we will clean out one well a year for every fifteen wells in operation. That is based on experience, and it virtually means that we will give Texoma wells one cleanout operation during their producing life. This cleanout cost is estimated at $1,260, and that divided by fifteen gives a unit cost of $84 for cleanout per well per year for 1939.

This cost in 1946 becomes $2,060 per well, principally on account of the fact that we contemplate by that time the use of acid in our cleanout operations. These unit costs reflect by the number of wells the total cleanout cost shown in the fourth column on page 8, and at the bottom half of the page these costs are divided in percentages in order to put them under the items of labor, materials, car and truck and contract labor. The contract labor item is shown as "Materials" on page 6-A. In working down the figures shown on page 6-A, it is necessary to use pages 7 and 8 in order to correlate them.

Page 9 is a detailed example of the effect of the computation of those quantities based on those unit costs, as, for example, under "Total Labor" in "Well Maintenance in 1939" will be shown the figure $1,827. On page 6-A, under "1939, Labor, Well Maintenance," is $1,827. Another illustration would be to take the car and truck expense. In 1939 the total car and truck expense will be $1,904, as shown on page 9. That is made up of $136 for the unit cost of car and truck expense, $1,468 car and truck expense incident to cleanout, and $300 incident to reclaim, and a total of $1,904. That appears on page 6-A under "Car and Truck Expense" in 1939 as $1,904.

We did the same thing for "Materials." The material item is shown in the upper right hand part of page 9, and shows for 1939 a unit cost of materials of $1,224; cleanout, $567; reclaim, $260; cleanout contract labor, $8,720, and reclaim, $1,509, making a total expense under that item of $12,280. Turning back to page 6-A and looking under "Materials" under 1939, we get $12,280. It is merely a work sheet to show the application of those factors.

Based on my experience in the discharge of my duties as general superintendent of production for Texoma Natural Gas Company, and the experience I had prior to going with the Texoma Natural Gas Company, and upon my knowledge of the conditions obtaining down there in that field and the problems to be met in connection with the production of gas for Texoma Natural Gas Company, it is my judgment that these costs of operation and maintenance reflected by this exhibit and shown on the different pages hereof will be incurred over the period of time indi-
669 cated in the exhibit, if the operations continue that long.

In this exhibit these costs, particularly the operating and maintenance costs, are projected on through the year 1954, at which time Mr. Bussard has concluded from his studies the pressures in the field will have reached an average of 25 pounds at the well head; but in bringing in these figures showing these costs down to that time I do not mean to imply that I believe that Texoma's property can be produced down to that pressure level.

Based on our experience in the Panhandle field, I am certain that operations cannot be continued to a pressure level of 25 pounds, because we have already found it necessary to abandon a number of wells at a much higher pressure. I have also had experience in other fields in which wells were abandoned at a much higher level, and I have had the opportunity to observe the operation of others in the Panhandle field, and it is my judgment that Texoma will not be able to produce its property below a pressure of 100 pounds.

In making this statement I am conscious of the fact that some falling off of Texoma's production will come about above 100 pounds. In other words, I do not think we shall operate at full capacity down to 100 pounds. We will have some restriction in the amount of gas available to the pipeline before we reach that point, and a tapering off will begin at an earlier period. There will be some wells that may be produced below the 100 pounds, but at a very much lower total quantity of gas than would be required for the pipeline. Therefore, it is my judgment that the 100 pounds is a point at which we can consider the operation of Texoma would be concluded.

In order to have a larger quantity of gas at pressures ranging from 100 pounds up to 125 or 150 pounds, we could drill additional wells if it were economical to drill them. We have made a study of that situation and we do not believe it is economical to drill wells in that bracket. We consider it economical to drill a well if we can get our money back with interest during its productive life, and when the pressure conditions and the open flow conditions in the field reach a stage where we cannot hope to produce enough gas from a particular well that we might drill at that time to pay for the well and pay for its operation and maintenance, that well will not be drilled.

These 215 wells that Mr. Bussard and I have agreed will be drilled represent the limit of the number of wells that I think will be economical from the standpoint of Texoma, in the light of conditions that obtain down there and which will obtain as this record shows.

(At this point counsel for defendants offered EXHIBIT 102 in evidence, and made the following statement:

This projection of these figures through the years 1952, 1953 and 1954, is due to the circumstance that we can rely only on the judgment of witnesses as to whether this project can extend beyond the year 1951. Mr. Bussard has brought in figures showing that the pressures 670 will have been pulled down to 25 pounds by the end of 1954. For the purposes of calculation we have put in what it will cost if it were possible to conduct these operations until the pressures reach such a level as that. However, Mr. Kesinger has testified, and now Mr. Dickinson has testified, that in their judgment these wells cannot be produced through the year 1954 but that production will stop prior to that time. Mr. Kesinger said two or three years prior, and Mr. Dickinson says to ground the average pressure at the well head of 100 pounds.

Now, we are entitled to have this record in such shape that if the Examiner were not to agree with Mr. Dickinson we would have some basis for computing the operating costs and the replacement costs down to such time as the Examiner finds that Texoma will be able to produce these properties, and it is a simple matter, if it should be deemed that Mr. Dickinson is correct and that these properties cannot be economically produced when the pressures reach 100 pounds, merely to chop off any expenses of operation or maintenance, or any capital expenditures, and the revenues also, after the time when it is found that we shall have reached the end of the life of this project. Upon offer of Exhibit 102 in evidence by Company Counsel objection was made by Commission Counsel to the introduction of the exhibit and to the witness' testimony with respect to it on three grounds, namely, the witness had testified he had no judgment as to what prices would be in the future, the exhibit and his testimony deals with a period of time beyond any period which can be deemed to be the reasonably immediate future, and, according to the witness' testimony it is inconsistent with Exhibit No. 91. Company Counsel in reply to the objections stated that the reason for the projection of the figures through the years 1952 through 1954 is due to the circumstance that only the judgment of witnesses can be relied upon as to whether the project can extend beyond the year 1951.)

Questions by the Examiner.

If operations should cease, taking a hypothetical case, in the year 1950, my estimates up to that point would be unaffected. My opinion as to the year when it will be necessary to cease operating is reflected in the chart which I introduced the last time I testified, showing the total withdrawals from the field cumulative at the point they cross Mr. Peterson's estimate of recoverable reserves at 100 pounds, which is the point at which I think we will cease operations. That chart is Exhibit 87.

I got that for the early part of 1948, but as we approach that period we begin a tapering off. As I explained, we will abandon some wells, and during the later years we won't reach our full requirements, and some requirements will be obtained below 100 pounds; but the effective abandonment pressure I have set at 100 pounds.

In other words, the withdrawal from the whole field would have been cut down prior to that time so as to defer the time when the pressures will have gone down to 100 pounds. As I recall the figures, that will be during the year 1951. I will check my figures and make a positive statement about that.

Questions by the Examiner.

The note on page 7 is to add $50 per year to operation materials, starting with 1944, for additional warehouse facilities. That is added into the total of the materials and is shown on page 6-A in addition to he other data that appears on page 7.

All of these reclaim items concerning labor repre-
671 sent simply the labor expense in reclaiming some
material.

If economical operations cease in 1951, that would not in any way affect the operation and maintenance expense up to that year. The rate of acceleration of decline would have something to do with changing those figures but in making our estimates we have tried to take into account the fact that there will be some decline in production in those later periods. I think Mr. Bussard and I both agree that there will be a rate of decline there.

(At this point EXHIBIT 102 was received in evidence over the objection of counsel for each of the Commissions, to whom an exception was allowed. Motion to strike witness' testimony denied.)

Cross-Examination by Mr. Slaff.

Under the item "Gas Acreage Rentals" this expense in 1939 will amount to $7,835 in 1940, $992; and in 1941, $720. At the end of 1941 Texoma will have under production all the leases it intends to keep and no further rentals will be required. That is to say, all the wells will not be drilled by that time, but in my judgment all the acreage will be under production. That would be reflected in the item "Gas Royalties" on page 6-A from that point on. The royalties are based on the total amount of gas which Texoma produces and are determined by the quantity of gas which Texoma does produce.

I have testified by affidavit in those gas proration cases which have already been mentioned, the same that Mr. Peterson testified in. I testified before the Texas Railroad Commission at one time in 1931 concerning the Common Purchaser Act, which had just been passed when we started operations in Texas. The extent of that testimony had to do with whether or not I thought a gas producer without a market outlet should be given part of Texoma's market. I did not believe so. I think that was in October, 1931.

672 R. G. STRONG, a witness for defendants, testified as follows:

Direct Examination by Mr. Hedrick.

(July 31, 1939)

My name is R. G. Strong. I live in Evanston, Illinois. I am 46 years of age.

I was graduated from high school in the spring of 1912. In November, 1912, I enrolled in the Machinist Apprentice Shop School of the Westinghouse Air Brake Company, Pittsburgh, Pennsylvania. The factory for this company is located at Wilmerding, Pennsylvania, a suburb of Pittsburgh. In connection with the shop practice obtained in this course, the Westinghouse Company conducted regular classroom work. In this connection I studied the subjects of mechanical drawing, shop arithmetic, trigonometry, analytical geometry, calculus, Steinmetz' theory of alternating currents, and also during my course at that time I had work as an instructor in the Y. M. C. A. night school, instructing in mathematics. I continued this course until 1915, at which time I completed it.

Immediately upon such completion, I secured employment with the same company as an assistant foreman in the manufacture of three-inch shrapnel shells for the British government. At the time the Westinghouse Company received this order, they did not have a building nor equipment available for the production of these shells. I assisted with the installation of all automatic equipment and with the initial tooling and final production of this order.

This work continued until September, 1916. At that time I enrolled in the engineering school of the University of

Michigan. At the time of my matriculation I received credit from the university for the mathematics and shop practice that I had received at the Westinghouse Air Brake Company. I attended the University of Michigan for the term 1916 and 1917.

Early in the fall of 1917 I secured employment as a foreman of the machine shop of the Aetna Chemical Company, Carnegie, Pennsylvania.

In December of the same year I left this company and enlisted in the U. S. Navy as a machinist's mate. After my two weeks detention period at the League Island navy yard at Philadelphia, I was assigned to duty on board the U. S. S. Maine.

In July of 1918 I passed an examination for admittance to the Fifth Officers Reserve Class to be enrolled that fall at the U. S. Naval Academy, Annapolis, Maryland. In September, prior to my enrollment at the academy, I received my commission as an ensign in New York City. In October I entered the engineering class of the Fifth Officers Reserve Class and during a four months' period I had an intensive course in U. S. naval marine engineering.

673 In February, 1919, I was assigned to duty on the U. S. S. Mississippi. While on board that ship I was responsible for the engineering performance record. I was also assigned as an assistant officer in the maintenance of all auxiliary equipment. My regular watches were stood in the main engine room, which happened to be steam turbines.

I was discharged from the U. S. Navy in July, 1919. In September, 1919, I obtained employment with the Empire Gas & Fuel Company, Bartlesville, Oklahoma. I was located at their camp near Eldorado, Kansas. My work was that of mechanical drafting and general machine shop practice in the Empire Company's machine shop. In July, 1920, I was given the position of superintendent of this machine shop. This also included supervision of the central heating plant, auxiliary electric power generating plant and the ice plant, and, two or three years later, the boiler shop department.

I continued in this capacity until April, 1926, at which time I was transferred to the engineering department of the Empire Companies at Bartlesville, Oklahoma. My work in that department consisted largely of general engineering problems, the major one of which was oil and gas pipeline construction.

Under the immediate supervision of Mr. E. V. Kesinger, I handled the details of the preparation of specifications and contracts, the awarding of contracts, ordering and shipping materials, and the direction of all field inspection of pipeline construction, and during this time made trips to the field to check the progress of pipeline construction and also to check the understanding that the various inspectors had as to the application of the specifications in connection with the pipeline construction.

Late in 1928 the Texas Pipeline Company and the Empire Pipeline Company formed what is known as the Texas-Empire Pipeline Company. This project consisted of the construction of a 12 inch oil pipeline from Cushing, Oklahoma, to Chicago. I was assigned to duty on the construction of this pipeline as supervisor of all field inspection.

I continued on this project until its completion in the early fall of 1929. At that time I returned to the engineering department of the Empire Companies at Bartlesville, Oklahoma, and was assigned problems relating to the initial development of the Texas-Chicago pipeline project. That is what is known now as Texoma Natural Gas Company and Natural Gas Pipeline Company of America.

During this preliminary work, until June of 1930, I specifically took part in the development of the pipe that ultimately went into the construction of the Texas-Chicago pipeline. In connection with this experimental work I assisted with the development of the physical and chemical properties of the pipe, and also assisted with testing to determine the weldability of the steel.

In June, 1930, I joined the Continental Construction Corporation and was assigned the duty of preparing 674 specifications, contracts, ordering materials, routing materials, supervising field inspection of the Texas-Chicago project. This work was all handled under the direct supervision of Mr. E. V. Kesinger, chief engineer, and Mr. S. E. Campbell, assistant chief engineer.

During the course of the construction of the Texas-Chicago pipeline I made frequent trips to the field to determine the actual physical conditions as they related to the construction of this pipeline. In July, 1931, I was given the position of superintendent of pipelines, which position I now hold.

My duties in this position consist of the operation and maintenance of the entire pipeline system, by which I mean the gathering system of Texoma Natural Gas Company, the main line of Texoma Natural Gas Company, and the main line and its branch lines of Natural Gas Pipeline Company of America. In this connection I am responsible for the transportation of natural gas from the time it leaves the well head until it passes our respective sales meters.'

In addition to my operation and maintenance activities, I also supervise all capital expenditures that are made in the pipeline department in the interest of both companies.

In addition to the mechanics of transporting gas from Texas to Chicago, a distance of approximately 900 miles, there are three factors which have constantly been a guide to me in supervising this maintenance program of the pipeline system. These factors are; safety of employees and of the public in general, protection of private and public property, and continuity of service.

The forces of nature, as well as other factors, are constantly working against this desired protection. Those forces are rain, floods, wind, drouth, landslides, earth tremors, lightning, snow, and ice. In the short life of this project we have experienced the effects of all of these forces in some degree.

On the average we have from 200 to 225 employees under my supervision. This number fluctuates considerably. We have had as few as 125 or 130 and as many as over 500 at a single time.

(At this point counsel for defendants presented a map entitled "Natural Gas Pipeline Company of America-Texoma Natural Gas Company: Map showing Location of Property, Pipeline Department." At the direction of the Examiner, the map was marked Exhibit 103 for identification.

Counsel for defendants also presented a map entitled "Natural Gas Pipeline Company of America, Map Showing Location of Property, Pipeline Department," and at the direction of the Examiner this map was marked Exhibit 104 for identification.)

I will first discuss Exhibit 103. The organization of
675 the pipeline department of Texoma Natural Gas Company and Natural Gas Pipeline Company of America has the entire line or entire system divided into three divisions. Each division is subdivided into two districts.

District No. 1 of Division No. 1 is known as the gathering system of Texoma, as shown on the large scale map, Exhibit 101.

The main line of Texoma is known as District No. 2, which begins at the Fritch compressor station and terminates at compressor station No. 2 near Gray, Oklahoma.

These districts are designated on the map by name.

District No. 3 is in the system of Natural Gas Pipeline Company and is that part of the pipeline which begins at compressor station No. 2 and terminates at compressor station No. 5.

District No. 4 begins at compressor station No. 5 and terminates at the Missouri River, south of Plattsmouth, Nebraska.

Exhibit 103 represents what we term the south half of the system.

Continuing on Exhibit 104, District No. 5 is divided into two subdivisions, 5-W and 5-E. 5-W represents the western half of Iowa, beginning at the Missouri River, proceeding east to a point south of Indianola, Iowa, and District 5-E is the eastern half of Iowa, beginning at a point south of Indianola, Iowa, proceeding in an easterly direction to the Mississippi River crossing south of Muscatine, Iowa.

District No. 6 is that part of the system in the State of Illinois, which also includes what we term the branch lines.

The Joliet meter and regulator stations are located at the eastern terminus of the 24 inch line, and they are also under my supervision.

Referring to Exhibits 103 and 104 and the designations on the left side of the exhibits from top to bottom, the top line shown in pink, entitled "Single Line Stream Crossings," refers to a number of stream crossings, to which reference will be made during the presentation of the pipeline exhibits.

These combination horizontal and vertical lines, and in some cases vertical lines, extending downward, show more specifically the location of these stream crossings with respect to the main 24 inch line, which is shown throughout in red.

The purple legend is entitled "Compressor Stations" and it shows the location of the respective compressor stations from 1 to 10, inclusive. The location of each station with respect to the pipeline is also designated in the same manner as has been explained.

676 The next horizontal line in red reads "Gate Valves."

A gate valve is, in general design, the type of valve which we commonly know of or see in oil, water and air service. In this connection it is a large piece of equipment specifically designed for this pipeline system; in fact, the valve was constructed in accordance with the specifications of the engineering department of this company.

These gate valves are nominally located every ten miles along the pipeline, with the exception of where a multiple line river crossing is encountered. At that place the multiple line river crossing gate valves are used in lieu of a main line gate setting.

Counsel has commented that between gate valve No. 7 and gate valve No. 11 the distance is something over two inches, while the distance between gate valve No. 6 and gate valve No. 7 is only a little over an inch, and has inquired if I mean that within the space between 7 and 11 there is a river header with a valve that we can utilize as a gate valve. At this location there is not a river crossing. Compressor station No. 2 serves as a block gate for that particular location. There is a main line valve in the pipeline at that point.

Continuing this example, there are two multiple line river crossings between main line gates No. 11 and No. 12, namely, Willow Creek and Beaver River. These crossings serve the same purpose as the main line valves as far as controlling the flow and stopping the flow is concerned in the pipeline system.

The main line gate valves are 24 inches in size. They are what we term a flange valve. They are steel constructed throughout. They were specially designed and constructed for this pipeline system. The inside working parts were all made of stainless steel. The valve alone is worth about $1200. and weighs two and one-half tons.

The numbers in the red circles designate the numbers of the gate valves as they are shown on the records of the company.

The next horizontal line in brown is entitled "Swage Drains." These drains are shown in a brown colored triangle over the entire system. The swage drain is a pipeline connection which is welded to the bottom of the 24 inch pipe to provide an outlet when coupled with a subsequent installation of a tank for the accumulation and removal of condensate.

The installation of the swage drains at the time this pipe line was being constructed followed the general procedure and practice of pipeline construction at that time. This company pioneered in the design and construction of a dehydration plant, the purpose of which was to remove the condensate from the gas before entering the pipeline system. At the time of the design of this line we had no idea what the efficiency of this dehydration plant would be. We have since learned through experience that the dehydration plant has been efficient and the subsequent use of the swage drains has not been needed.

677 We have started a program of removing and reclaiming these swage drains. All of them have now been removed from the main line of Texoma Natural Gas Company between compressor stations Nos. 1 and 2. That reclaiming or removing is designated by the word "Reclaim" or the abbreviation "Rec.," which will be noted under each swage. Additional swages have also been reclaimed from the pipeline system. The same notation of "Reclaim" has been made. The number in each one of those triangles is the number which has been assigned by the company to each one of those swage drains, and that number is as it appears on the records of the pipeline company.

Cross-Examination by Mr. Slaff Interposed.

After we retire them from plant and service we put the usable material in warehouse stock and junk the remainder. We have found the gate valve and the flanges to be usable; but I cannot say offhand what percentage that is of the material.

Direct Examination by Mr. Hedrick.

The next horizontal line, shown in orange, indicates the installation of drips under the entire pipeline system. The drips are also numbered and are so shown on the records of the pipeline company. The "Rec." under some of the drip numbers means "Reclaim" as I described it with reference to swage drains. A number of the drips have now been reclaimed due to the fact that they were no longer needed for the purpose for which they were installed, and also to the fact that they represent, as they were constructed, a hazard to pipeline operation.

The bottom horizontal green line, or last line, is entitled "Multiple Lines Stream Crossings." That shows the location of each multiple line stream crossing, that is, each stream where there are two or more pipelines installed. The three lines at the locations of the multiple line crossings are only a legend used on this map to designate a multiple line crossing, and have nothing to do with the number of lines involved.

Exhibit 103 contains a red line which is fairly straight across the map but when we get over here to the east end of the exhibit the line, instead of being straight, swings down to the south for a couple of miles and then up again where it crosses the Missouri River. That is a location where rights of way could not be secured to project a straight line, which necessitated a deviation to the southeast. In other words, instead of continuing the line straight on across to the Missouri River, we brought the line around those places where we were unable to secure rights of way from landowners.

On Exhibit 104 the red line which designates the pipeline is not as straight generally as it was shown on Exhibit 103. The pipeline as it proceeds across the States of Iowa and Illinois deviates more or less from a straight line. There are two reasons for this, one of which was our inability to secure rights of way, and the second is due to certain physical conditions of topography which prevented the
678 construction of a straight line, such as the particular roughness of the country across Iowa and certain portions of Illinois. In other words, when we came to a bad hill or bluff or some other physical obstruction in the terrain, instead of building the line up over that obstruction we went around it, if it accomplished better pipeline construction.

We have a program for the removal of swage drains and alteration of river crossings, the details of which will be brought out as we proceed.

I have complete supervision of the gathering system of Texoma Natural Gas Company as shown on Exhibit 101, with the exception of the property at Fritch and the individual wells, which come under the production department. I have supervision over the 24 inch main gathering line and the lateral lines leading from the wells to the main trunk line. Exhibit 101 represents a true picture of the main trunk gathering lines and lateral lines of Texoma as they exist at the present time and are shown in black on Exhibit 101.

The swage drains which have been removed and will be removed in the future, and also some of the drips which have been removed, have been used by the company in the past.

(At this point counsel for defendants offered in evidence EXHIBITS 103 AND 104, and they were received in evidence without objection.

Counsel for defendants then presented a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Additional Capital Expenditures, Pipeline Department. Witness, R. G. Strong." At the direction of the Examiner, this document was marked Exhibit 105 for identification.)

Exhibit 105 represents amounts to be expended as additional capital expenditures by Natural Gas Pipeline Company and Texoma in the pipeline department, of which I have jurisdiction and supervision.

On page 1 of Exhibit 105, under the heading "Additional Capital Expenditures," where the word "Texoma" appears, those additional capital expenditures of Texoma Natural Gas Company, of which page 1 is practically a recapitulation, are shown in more detail on page 2 of the exhibit, and the line entitled "Natural Gas Pipeline Company" is explained in more detail on page 7 of the exhibit.

Under the heading "Book Cost of Equipment Retired" the retirements of Texoma Natural Gas Company and Natural Gas Pipeline Company are shown, and these are explained in more detail on pages 2 and 7 respectively of Exhibit 105.

The items shown under the heading "Salvage" are explained in more detail on pages 2 and 7 respectively of the exhibit.

The number of years in the first line represents the
679 years during which the expenditures shown will be
made, and the additional capital expenditures to be made during those years are shown in recapitulation form directly below the designated year.

Turning to page 2 of Exhibit 105, line 1, entitled "Gathering System," line 2, entitled "District No. 2," line 3, entitled "Booster Stations," and line 4, entitled "Tools," are explained more in detail on pages 3, 5, 4 and 6, respectively, of Exhibit 105.

Under the heading "Retirements" the retirements of gathering system, District No. 2, booster stations, and tools are explained more in detail on pages 3, 5, 4 and 6, respectively, of the exhibit; and the same is true with respect to the sub-heading "Salvage."

The amounts to be expended for these different items designated on page 2 are set out for each year during that period of time under the headings 1939 to 1954, inclusive.

The information as to the lateral lines to be constructed by Texoma Natural Gas Company from 1939 to 1951, inclusive, and also as to item No. 2, entitled "Meter Houses," was obtained from Mr. R. M. Bussard of the engineering department, under Mr. G. M. Davidson's supervision, as chief engineer and superintendent of operations. The information which I received from Mr. Bussard and Mr. Davidson is contained in Exhibit 100, which was introduced in evidence during the testimony of Mr. Bussard.

The lengths of line, the sizes of the line, and the location of the lateral lines to be constructed are shown in Exhibit 100. These future gathering lines shown on Exhibit 100 are shown in red lines in Exhibit 101.

After Mr. Bussard gave me that information, it was my responsibility to develop the costs of constructing each of the lateral lines as shown in Mr. Bussard's Exhibit 100; and throughout this entire Exhibit 105 I used prices for labor and material going into the additional capital expenditures by the two companies as of June 1, 1939.

After getting the information from Mr. Bussard I proceeded to calculate the cost of constructing each one of the lateral lines shown in detail in Exhibit 100 and depicted on Exhibit 101, and the figures set opposite line No. 1 on page 3 of Exhibit 105 for the years 1939 to 1951 represent the capital expenditures to be made for the construction of lateral lines shown by Mr. Bussard's Exhibits 100 and 101 in each of the respective years 1939 to 1951, inclusive.

Line 2 is entitled "Meter Houses." A meter house is a small corrugated, galvanized iron building, constructed on a steel framework. The size of this building is six feet wide, eight feet long, and seven feet high. The purpose of this building is to house the orifice meter gauge. One of these houses, which includes the meter setting, is constructed at each well immediately upon its completion.

680 The number of wells to be drilled by Texoma Natural Gas Company beginning with 1939 and terminating in 1951 was given to me by Mr. R. M. Bussard and is contained in a tabulation presented by him marked Exhibit 100. After I received the information as to the location of these wells, I assigned a meter house to each well. The cost of a meter house as represented by this exhibit is $139. I do not know the total figure as to how many will be built

in the years 1939 to 1951, inclusive; but it is in Mr. Bussard's exhibit. I have the figures by years.

In 1939 we will connect 22 wells; in 1940, 20 wells; in 1941, 20 wells; in 1942, 20 wells; in 1943, 20 wells; in 1944, 20 wells; in 1945, 18 wells; in 1946, 19 wells; in 1947, 18 wells; in 1948, 16 wells; in 1949, 12 wells; in 1950, 9 wells; and in 1951, 1 well.

It is quite necessary that meter houses be constructed over each meter for the protection of the meter itself and the equipment contained within the meter house from weather conditions.

Line No. 3 is entitled "Construct Bridge Across Big Blue Creek," and shows an expenditure in 1942 of $54,508. Big Blue Creek, which is referred to as item No. 3 on page 3 of Exhibit 105, is located on the Bennett ranch in Moore County, Texas. This creek is now crossed with a single 24 inch pipeline. During the past few years we have had considerable maintenance expense at this crossing for the purpose of protecting the 24 inch line and the continuous flow of gas through the line. These expenditures have been made for the protection of the banks from erosion and for the protection against erosion of the stream bed and the widening of the stream. We have used such facilities as concrete wing walls, concrete anchors around the pipe, split steel reinforcing sleeves around the couplings, and what is known as jetty protection.

This work has been only partially successful. The width of the channel at the present time is 356 feet, which indicates an increase of 60 feet since 1931, which is the approximate time the river crossing was first constructed. This stream normally carries a very small amount of water. In fact, it can be jumped across at times, or easily waded. Due to the topography of the drainage area, the drainage from rains is very rapid. In fact, this stream can change from a very small quantity of water to one of turbulent intensity, having a depth of 12 to 16 feet.

The bed of this stream is sand with a depth of approximately ten feet, resting on a shale sub-surface. During these flood periods the entire body of sand moves en masse downstream. The forces thereby developed against a structure such as a pipeline are obvious.

I desire to relate an experience that we have had with our gathering system crossing at another point on this same creek, which is on the Sneed ranch, and is located southeast of the Bennett ranch. This crossing was originally constructed with two 18 inch parallel submerged pipelines. In 1935 we experienced one of these floods which I mentioned. As a result of that flood the upstream 18 681 inch pipeline failed or broke in two at the south bank. We then started to reconstruct that crossing. Before the work was completed we had a second flood which completely reversed the arc of the pipe from an upstream arc to a downstream arc. We were then convinced that it would be futile to spend additional money at that crossing for a submerged crossing. As a result of that, we decided to construct a suspension type bridge. A picture of that bridge was introduced through the witness Floyd C. Brown and is marked Exhibit 78.

The present suspension bridge across Big Blue Creek in Moore County, Texas, is located on the Charles Ragsdale survey block on the Sneed ranch. It is approximately six miles north and west of the Moore County Canadian River crossing at the point I am indicating on Exhibit 101. The crossing of Big Blue Creek with the single 24 inch line, at which place a suspension type bridge is planned, is located on the W. E. Bennett ranch, which is in Section 3, Block M-1, Moore County, Texas.

Page 18 of Exhibit 105 represents the amount of river work that has been done by Texoma and Natural Gas Pipeline Company from the time the original line was constructed in 1930 and 1931 to January 1, 1939. The description of this work is shown by the respective pipeline district numbers. The year is given in which the work was performed, the county and state are also shown, and the actual costs of the work performed. Some of this work was maintenance work. It does not all represent capital expenditures.

Questions by the Examiner.

Prior to 1935 on the Big Blue River crossing we had two 18 inch lines, and it was then changed to a bridge. After constructing the bridge we then installed two 18 inch lines on the bridge. We originally had two 18 inch lines submerged across the creek or river. We still have two 18 inch lines across the stream on the bridge.

The Big Blue crossing on the Bennett ranch is becoming increasingly important. This is due to the fact that there will be additional production from those sections of Moore County to the west, northwest and southwest of the Big

Blue crossing In order to safeguard the delivery of this gas and provide for continuity of service, we are going to construct a suspension type bridge across this stream in 1942, at an expenditure of $54,508. We will also construct on this bridge two 18 inch parallel lines.
(August 1, 1939)

Direct Examination by Mr. Hedrick.

Yesterday Mr. Slaff asked me a question concerning Exhibits 103 and 104. As I recall the question, it was what percentage of the material salvaged from the reclaim of a swage drain was usable, and I replied that I didn't know but that I would get the information. I was in error when I answered the question, due to the fact that I had in mind the usable material salvaged from the reclaim of a drip instead of a swage drain. There is no salvage from a
682 swage drain; it is all junked.

I wish to advise further with respect to the Big Blue Creek crossing. This is Big Blue Creek on the Bennett ranch in Moore County, Texas. Just before coming over this morning I had a report from the operating superintendent in Texas, who advised me that floods within the past two or three days have caused additional damage at that crossing to the extent of about $1000. This is further evidence of the forces of nature which are continually acting against the maintenance of a pipeline system. The results of these forces cause a considerable portion of our continued expense.

I did not get a complete report this morning of the nature of the damage, only that the river was wider than it had been known to be before; and I assume that more of the pipeline will have to be anchored and more of the couplings will have to be sleeved in order to stabilize the line at that point.

On line 4, page 3, of Exhibit 105 is a provision for an expenditure of $167,482 in 1940 to construct two 12 inch Canadian River lines. This Canadian River crossing is the Moore County lateral of the Texoma gathering system. On Exhibit 101 the Moore County lateral crossing to which I refer is about two miles northwest of the Fritch compressor station. All the gas from the Moore County area is required to pass across that river at that point before reaching the Fritch compressor station.

This is on the Moore County 24 inch lateral where it crosses the Canadian River. This river is crossed with four 12 inch pipelines. Each line is approximately 7,000 feet long.

The Canadian River has a water shed or drainage area above the pipeline crossing of over 23,000 square miles. This drainage area is quite rough as to topography. The slopes are steep. It is semi-arid; which has been aggravated in the past few years on account of the drouth conditions in the southwest country. Rains, when they do occur, rapidly flow to the drainage areas and to the creeks, and hence to the main stream, the Canadian River.

It is not uncommon to see a flood approaching down the channel in the wall of water stage. By that I mean there is a distinct wall of water three to four feet in height. Preceding this approaching flood you will observe a boiling of the sand, as there is a very strong subsurface flow. The total depth of the sand in the Canadian River channel has never been found. There is a stratum of sand approximately 25 feet in depth, which is known as floating sand. This stratum is completely saturated with water during flood conditions. The sand moves en masse downstream during heavy flood. The force of this moving body of sand is sufficient to shear off bridge piers, piling, power line poles, break pipelines, and do damage of that character.

By way of explanation I would like to cite for you 683 some of the damage that was done by the Canadian River in the vicinity of our pipeline crossing as a result of floods during May and June in 1937.

The stream at the top of the picture on Exhibit 92 is the Canadian River of which I speak. If you will refer to that photograph you will observe the route of the 24 inch pipeline running from the Fritch station northwest across the Canadian River. We are accustomed to speaking of it as the main trunk line rather than a lateral line. It runs to Moore County.

You can follow the back fill by that lighter line across the photograph. The line enters the river at the south bank at the point I am indicating on the picture, approximately two inches in from the righthand margin, and leaves the river on the north bank about one inch from the righthand margin.

As a result of these floods of 1937, the Canadian River Gas Company lost four 8 inch lines on May 29, 1937. This crossing is about three and one-half miles upstream from our Canadian River crossing. The Phillips Petroleum Company lost four piers of their pipeline bridge and other piers were damaged. This bridge carries a 24 inch line. The Phillips Company's bridge is three-quarters of a mile downstream from our main line Canadian River crossing. The Huber Petroleum Company's 16 inch single line failed during one of the first rises. This crossing is three and three-quarters miles downstream from our main line Canadian River crossing.

I have referred to downstream. So that the record will be clear as to what I mean by downstream, I will explain that the Canadian River flows from the southwest toward the northeast.

The Southern Union Gas Company's 4 inch line parted at the center of the stream. This crossing is located three miles upstream from our Moore County crossing.

The Phillips Petroleum Company lost an 8 inch and a 12 inch line crossing the Canadian River near Sanford, Texas. These lines were located two and one-half miles downstream from our main line crossing.

The Rock Island Railroad Company's bridge near Sanford, Texas, was damaged to the extent of 250 feet. That is, 250 feet of bridge was washed out, and numerous piers were weakened. This bridge is downstream from our main line crossing. It is near Sanford, Texas, which is about a mile east of our Canadian River main line crossing. The Rock Island bridge is about two and one-half miles downstream from our main line Canadian River crossing.

There was additional damage done during the same floods on other streams in that same area, which I will not take time to detail now.

I wish to refer to a pipeline break which we had on the main line crossing of Canadian River in August, 1935.
684 We had Line No. 5, which is the fifth line counting from the downstream side, break. This line completely failed and broke in two at the north bank during a flood which reached a height of about eight feet.

We have checked the movements of the lines at the Canadian River main line crossing, and they have settled to depths of 15 feet and have moved downstream to the extent of 20 feet. On the Moore County crossing the downstream movement of the 12 inch lines has amounted to eight feet, the vertical movement to six feet. These movements are caused by the forces of this stratum of floating sand, which is approximately 25 feet deep.

When these lines move downstream there is a cold working of the metal which takes place. I mean that when a piece of metal is bent or deformed above the yield point of the steel, a new yield point is obtained. With each successive movement or cold working of the steel there will continue to be a new yield point until ultimately that yield point will reach the tensile strength of the metal. As each successive yield point is reached, the metal becomes more brittle, that is, more subject to fatigue, due to the vibration of the floating sand and of the water. This fatigue condition will eventually cause complete failure of the steel. Fatigue is caused by varying forces applied gradually, not by impact; and the resulting loads will cause the metal to fail at amounts of one-half to two-thirds less than the ultimate strength of the steel. If these variations in load are increased, and the repetitions are increased, the metal will fail at loads less than one-half of the ultimate strength of the steel.

I would like to cite a few examples of fatigue or the development of fatigue. I will assume first a sixteen gauge steel wire held between two hands. We have very frequently wanted to break a piece of wire in two pieces by bending it back and forth. If we bend this wire at small angles of deflection at a slow rate of speed, slow reversals, it will take some time for that wire to fail. We soon get tired of that and we speed up the operation. We increase the angles of deflection and increase the speed or number of reversals, and the wire will soon fail. If we take the same wire and attempt to break it by tension, it would be impossible for a human to do it without superhuman strength.

The cracks which appear in the fenders of our automobiles are the result of fatigue. We frequently read of railroad wrecks which are attributed to or caused by a break in the rail. This break is caused by or is the result of fatigue. The rail contains a flaw or defect from the time of its manufacture. The defect progresses or grows by the continuous travel or pounding on the rail by the wheels of the trains which pass over the track. The result is ultimately the broken rail.

To show how little a force may be to cause metal fatigue, it is known that the water dripping from a drainpipe in a railroad car into the axle of a truck will ultimately cause that axle to fail.

These examples are given to show and to explain the forces which are continually working on these submerged crossings.

685 As stated, the Moore County crossing is now laid with four 12 inch lines. At the time of its original construction in 1931, we made provisions for the installing of two additional 12 inch lines. The header and gate valve facilities are now in place. Due to the additional drilling which is scheduled to be done in Moore County and the additional amount of gas that will be delivered from the Moore County area, in 1940 we are going to lay two additional 12 inch lines. These lines will not only serve as additional protection to this crossing, but will also reduce the pressure drop which now exists at that place. We contemplated these two additional lines at the time we constructed this crossing, and provided for additional spaces on the header.

The next item is No. 5, entitled "Replace Drips, 24 inch Line," with expenditures in the years 1940 to 1954, inclusive. A drip is a facility for the collection and removal of condensate from a gas pipeline. The drip to which I refer consists of a tank 18 inches in diameter which is placed directly beneath and parallel to the center line of the 24 inch pipe. This tank is connected to the 24 inch line by means of two 10 inch vertical risers. By risers I mean 10 inch pipe. The ends of each of these two pipes are welded respectively to the tank and to the 24 inch line, the bottom of the 24 inch line. These 10 inch welds are reinforced with gusset plates.

(At this time counsel for defendants presented a document containing three photographs, the top one being labeled "Drip With Gusset Type Weld Reinforcement," one entitled "Split Steel Welding Sleeve Installed on 24 inch Coupling," and another, "Illustration of Gusset Plate Reinforcing; Not a Part of a Drip." At the direction of the Examiner, this document was marked Exhibit 106 for identification.)

The picture at the top of Exhibit 106 gives the end view of a drip. The drip is placed on its side. The pipe to the right of the picture represents the 24 inch line. The pipe of which you see the end at the left of the picture represents the 18 inch pipe. The pipe connecting these two pipes is the 10 inch pipe. At each end of the 10 inch pipe is a triangular shaped plate. This is known as the gusset plate. Four of these plates are installed at 90 degrees around the periphery of the 10 inch pipe.

This gusset plate can be better observed by referring to the lower right hand picture on Exhibit 106. That shows the method of welding the gusset plate to the riser and to the pipe. These drips are continuously subjected to fatigue, which has been previously explained. The purpose of the gusset plate is to reinforce the pipes where they have been weakened as the result of the removal of a section of pipe from the tank and the 24 inch line.

We will assume an 18 inch tank closed at the ends with ellipsoidal heads with pressure applied on the inside. There are circumferential lines of stress running around the pipe. There are also longitudinal lines of stress running from end to end. We cut a hole in the pipe for welding a 10 inch riser. A 10 inch piece of pipe is welded to the opening and is closed at the opposite end. These
686 circumferential lines of stress as they approach this opening separate and follow the edges of the hole. In other words, those lines of stress are concentrating at the edges of the hole which has been formed, and in a similar way the longitudinal lines of stress are separating and concentrating at the edges of the hole. The pressure down in that drip is the same as the pressure in the pipeline itself, and also in the 10 inch risers to which I have referred.

There is a continuous deformation of this metal due to the pulsating flow of the gas. That is, the metal is continuously working at the points where the gusset plates are welded to the pipe. We have actually had failures occur in headers at the Fritch compressor station and also at Station 6. We have a program for removing and replacing these drips in the gathering system on account of this fatigue and on account of external corrosion.

In 1940 we will replace three drips amounting to $3,673 and in the succeeding years, from 1941 to 1954, inclusive, we have a continuous program of replacing drips on the 24 inch trunk line of the entire gathering system. The drips which will be constructed to replace the present drips will be so designed as to be reinforced with a steel welding saddle.

(At this point counsel for defendants presented a document containing two pictures, the top one of which is entitled "Drip with Saddle Type Weld Reinforcement," and the bottom picture being entitled "Welding Saddle Reinforcement." At the direction of the Examiner, this document was marked Exhibit 107 for identification.)

Both of the pictures on Exhibit 107 represent the saddle type construction to which I refer. In the upper picture the two large pipes in the center of the picture connected with two smaller pipes represent a drip of the type with which we intend to replace the gusset type of drips. The lower picture is a close-up view of the saddle reinforcement.

(At this point EXHIBIT 107 was offered and received in evidence without objection.)

The replacement cost of these drips varies from $1,191 to $1,291, installed complete.

Line 6, entitled "Replace lateral drips," shows expenditures from 1946 to 1954, inclusive. The lateral drip is a drip installed in the lateral lines. These lateral lines vary in size from four inches to ten inches, and when I refer to lateral lines I mean to distinguish from the 24 inch trunk gathering lines to which I referred a moment ago. The lateral lines are the smaller lines leading off from the main trunk gathering lines to the wells or to groups of wells.

These drips are constructed with 18 inch pipe closed at each end with an ellipsoidal head. They are installed in a vertical position in the pipeline—in the lateral line. 687 The lateral line is welded to the upper portion of the drip. These drips are installed in low swales, in creek areas, so that the condensate which is flowing along the bottom of the pipe line in a liquid phase will drop out by gravity into the drip tank, from which it will be later removed by the chart changers or line walkers.

By necessity, these drips are located in areas which are subject to accelerated corrosion. Due to the corrosive action at these locations on the metal surface of the drips, we are going to replace these drips beginning in 1946 and ending in 1954. The expenditure in 1946 will be $1,418, which will include 12 drips. I have referred to the difference in cost, ranging from $1,191 to $1,291. The difference in cost accounts for the little variation in the figures shown. In 1944, $1,266 is for one drip. That is another point that I did not observe before. That little variation in cost is explained by the expense of excavation.

I have referred to corrosion and its effect on the pipeline. Corrosion is the physical loss of the weight of metal caused by uniform or non-uniform oxidation, commonly known as rust. This corrosion is aggravated by the galvanic action of the soil and pipe and by stray electrolysis.

(At this point counsel for defendants presented a piece of steel about six inches square. At the direction of the Examiner, this piece of steel was marked Exhibit 108 for identification.)

The piece of pipe metal referred to as Exhibit 108 was removed from the main 24 inch pipe line at the highway crossing north of the Arkansas River crossing east of Dodge City, in Kansas. The smooth part is that portion of the pipe which was inside the 24 inch coupling. The rubber of the coupling extended over this part which has not been affected by corrosion; that is, from the smooth edge about two inches to where we see a depression in the metal.

The remaining portion of the pipe, of which this is a section, was corroded to depths of approximately one-eighth of an inch. The remaining metal thickness is about three-sixteenths of an inch. At the time this was removed from the line we removed 45 feet of 24 inch pipe. The bottom segment of this pipe was corroded in a similar manner as is shown on this sample. We are continually inspecting railroad and highway crossings to determine the extent of corrosion. There was no break at this point. That condition was found as the result of one of our regular inspections.

That condition in the pipe presents a hazardous situation with reference to the pipe line. That corrosion is caused by galvanic action aggravated by the presence of water, and is more commonly known as the electro-chemical corrosion. The hazard is, we may explain, twofold. A failure of the pipe would result in a serious interruption of the flow of gas, and a failure of the pipe at that location, being adjacent to a highway, could result dangerously to traffic on the highway.

We have found through our inspections that the pipe coating has not been resisting the effects of corrosion
688 as well as it should. The operations of constructing a highway or railroad crossing are such that it is difficult to construct a crossing and maintain the full value of the protective coating, so we have paid particular attention to the crossings. We make inspections of the rest of the line as well.

This is a typical case of corrosion. That condition is more or less local along the pipe line. It does not exist continuously. When corrosion starts, it will progress, but not in a straight line curve. The rate of progression depends entirely upon the local and specific conditions that exist at each point along the pipeline.

I have completed my explanation of Item 6, and will proceed to Item 7, entitled "Install Tank Drips on 24 Inch Line," and showing expenditures from 1940 to 1952, inclusive.

At the time the 24 inch main trunk line was constructed in the Texas Panhandle in 1931, we made provisions for the installation of what we termed tanks. A tank is a reservoir which is constructed out of pipe, with the ends closed, with ellipsoidal heads. During the course of operating the gathering system we developed, through operating experience, that condensate will accumulate at points where no means for removing the condensate have been provided. At those places we install tank drips, and they are only installed at such times as we determine condensate is actually accumulating at those respective locations.

Beginning with 1940, we will install tank drips to and including 1952. The expenditure of $252 in 1940 is for the installation of two tank drips. The cost of one tank drip, completely installed, is $126. The amount varies with the number of drips installed. In 1945, 1946 and 1947 there will be three tank drips installed in each of those years, which will make a total of 29 tank drips installed during the 13 year period.

Item 8 is for installing new drips and tanks on lateral lines. It shows expenditures in 1943 to 1952, inclusive. My explanation for the installation of those drips is the same as that concerning Item 7 except that there will be additional condensate to be removed from the lateral lines as the field becomes older and the individual wells produce more water and moisture.

Question by the Examiner.

These figures represent tanks to be installed at five locations on the lateral lines, and 160 new drips will be installed on the respective lateral lines.

Direct Examination by Mr. Hedrick.

The expenditure of $1,880 in 1943 includes the construction of 16 new drips during 1943. The same number will be installed in 1944, 1945, 1951 and 1952. During the years

1946 to 1950, inclusive, we will install 16 new drips and one tank drip in each of those years.

689. Item 9 covers meters and regulators. These will be installed during the years 1939 to 1951, inclusive. Each time that a gas well is completed, it is necessary to install an orifice gauge meter and a regulator. The meter is used for recording the flow of gas from each well. The regulator is used for reducing the lateral line pressure to a four ounce pressure for the furnishing of gas to a heater which is installed on the inside of the meter house. This heater is used in the winter months to protect the meter gauge lines from freezing, which, if they did, would give an erroneous meter reading or registration.

The number of meters and regulators to be installed will be the same as the number of wells to be drilled in each of the years 1939 to 1951, inclusive. This is with the exception that in 1942 we will drill 20 wells but only purchase 15 meters and regulators. This is due to the fact that in 1942 we will reclaim five meters and five regulators which are now in service and which will make those facilities available for further installation. By referring to Exhibit 100 one could tell the number of meters and regulators that will be installed, since they are in harmony with the number of wells that will be drilled during the years in question, except for the year 1942.

Referring back to lateral drips, Line 6, and tank drips, Line 7, on the gathering system the gasoline has not at that time been removed from the gas, so there will be a larger amount of gasoline and moisture in the line at those points than after the gas leaves the Fritch station.

The unit price of those meters and regulators is $151, and you can tell by using that divisor how many are installed. In Line 9 on page 3 of Exhibit 105, starting with the year 1939, the number of meters and regulators to be purchased is as follows: 22 in 1939; 20 in 1940; 20 in 1941; 15 in 1942; 20 in 1943; 20 in 1944; 18 in 1945; 19 in 1946; 18 in 1947; 16 in 1948; 12 in 1949; 9 in 1950; and 1 in 1951.

Item 10, page 3, of Exhibit 105 is entitled "Skellytown Camp." Under that item we propose to construct a camp for the housing of personnel and equipment for the operation and maintenance of that part of the gathering system which is and will be in the vicinity of Skellytown, Texas. As additional wells are drilled and booster stations are installed, it is necessary to place our employees and equipment closer to the vicinity of their actual work.

In 1942, in Skellytown, we show an expenditure of $18,580. The detail of that expenditure includes the following: one house for a meter inspector; one house for a chart changer; a four car garage; the purchase of a camp site; the completion of a water well and installation of pumping equipment; an elevated water tank; a septic tank; and a pipeline warehouse.

In 1943 the expenditure of $746 is for the installation of pipe rocks for storing a supply of pipe. The expenditure
of $19,433 at Skellytown in 1944 will be divided as fol-
690 lows: one house for a foreman; one house for a truck
driver; two houses for maintenance men; six garage stalls; and recreation facilities.

In 1947 we have an expenditure of $5,547 at the Skellytown camp, which is for the construction of one house for a maintenance man and the construction of two garage stalls.

In 1948 we have an expenditure of $10,043 at Skellytown for the construction of one house for a maintenance man, one house for a chart changer, and two garage stalls.

The recreation facilities item on line 10 includes such facilities as a tennis court, croquet court, or teeter-totters for children. The amount involved for recreation facilities is $350.

Line 11 on page 3 of Exhibit 105 refers to the construction of houses and facilities at the Dumas camp, located adjacent to the town of Dumas, Texas. The reasons for increasing the facilities at the Dumas camp are the same as have been explained for Skellytown. In 1940, at Dumas, we have an expenditure of $36,061, which includes the construction of the following: a house for a foreman; one house for a truck driver; two houses for maintenance men; one house for a meter inspector; one house for a chart changer; a ten-car garage; three bays added to the present warehouse; a water well and complete pumping equipment; an elevated water tank; and recreation facilities in the amount of $350.

In 1942, at the Dumas camp, we have an expenditure of $4,655, which includes the construction of one house for a maintenance man, one garage stall, and the purchase of additional land at a cost of $163.

In 1943, at the Dumas camp, we have an expenditure of

$4,429, which includes the construction of one house and one garage stall.

In 1945 we have expenditures totaling $5,299 for the construction of one house for a chart changer and three garage stalls.

In 1946 we have an item of $4,080 for the construction of one house for a maintenance man.

In 1947 we show an amount of $4,757 for the construction of one house for a meter inspector and two garage stalls.

Line 12 on page 3 of Exhibit 105 is described as Kingsmill Camp. During 1943 we have an expenditure of $5,337 for the construction of one house for a chart changer and a two-stall garage.

Item 13 is entitled "Cathodic Protection," and shows expenditures in 1941 and 1942. Cathodic protection is an electrical method for preventing the corrosion of metal by impressing a negative potential on the pipe with respect to the soil or some other structure. That cathodic protection is on account of either electrolysis or electro-chemical action. When pipe is corroded by either of those, the corrosion is due to the current flowing from the pipe.
691 The pipe is positive to the soil or some other structure.

The cathodic method is for the artificial reversing of the flow of current. The equipment that is used is a power-driven generator. The power may be supplied by a gas engine or a windmill, or the power can be purchased from some electrical transmission line.

We will assume, for example, the installation of the windmill type of equipment. A unit of this kind is installed on a tower similar to a windmill tower. A ground bed is installed at a point remote from the pipeline. The current flows from the generating unit to the ground bed, thence to the pipe; that is, there is always a continuous flow of current from this ground bed to the pipe.

We have an installation of cathodic protection which is being made at the present time on a five-mile section of 24 inch line near Wilson, Kansas. We will have sections of the line, each section being one mile or more in length, located in concentration areas wherein cathodic protection will afford an economical method for arresting the action of corrosion. We have had experiments made and studies prepared in the past showing that electrolysis or electrochemical action does exist and that this method is an efficient method for protecting the pipeline against such action.

Questions by the Examiner.

We plan to generate our own power. The figure in 1941 is for the purchase of equipment for the protection of 3.8 miles of lateral line and two miles of 24 inch pipe line. It will consist of the wind driven generator, tower, ground bed, necessary wiring, and, in the case of the 24 inch pipe line, the copper bands which are installed at each coupling. They are welded to the pipe on each side of the coupling to provide for a continuous flow of current, thereby reducing the resistance of the pipe. We have not yet specifically located those sections; but we have determined their length from a study that we are making at the present time and work that we have done in Kansas during these last few years. That length is the result of those studies, based on a percentage of the amount of pipe installed. Those sections which are referred to here will be in the gathering system in the Panhandle field in Texas.

Direct Examination by Mr. Hedrick.

The equipment involved in the expenditure in 1942 is the same and we plan to protect a similar amount of pipe. It will still be in the gathering system in Texas.

On page 3 there are two other sub-heads, namely, "Book Cost of Property Retired" and "Salvage." Those are the amounts set out opposite each of the lines under those subheadings shown on page 3. For example, in 1942, under the heading of "Book Cost of Property Retired," Item 1, lateral lines, we show a property retirement of $7,500. In the same year under the heading "Salvage" there is an item of $1,800. That is the salvage that is involved in the
taking up of the lateral lines involved in the construc-
692 tion of lateral lines in Line 1 under the heading "Addi-
tional Capital Expenditures," and refers to the book
cost of the usable material.

(At this point EXHIBIT 108 was offered and received in evidence without objection.)

The information as to the stations to be installed and the units added, shown on page 4 of Exhibit 105, was obtained from Mr. R. M. Bussard, and is the information that is contained in Exhibit 100. Those booster stations are spotted on Exhibit 101 and are designated by solid red triangles.

The term "Stations Installed" means the construction of a building and the installation of an engine driven compressor unit. The term "Units Added" means the unit or units that may be added to the original station installation. The first line on page 4 of Exhibit 105 gives the number of stations to be installed in each of the years there shown. The second line indicates the number of engine driven compressor units that are to be added to the respective stations. When I say "Units Added" it means the same as the engine with its compressor unit referred to by Mr. Bussard. The terms are synonymous and refer to a 40 horse power complete unit. "Stations Installed" and "Units Added" compare to the "Stations Installed" and "Units Added" shown in Mr. Bussard's Exhibit 100. In other words, in 1940 there will be two stations installed in addition to the station that is now installed; and in 1942 an additional 12 stations will be installed, and in one of those stations an additional unit will be added, so that at one of the stations you will have the housing and contained in that housing will then be two units.

I have been requested to explain how I arrive at the cost of the stations installed and units added, and how much each unit costs as of June 1, 1939. In the year 1940 we have an expenditure of $10,640 for the installation of two stations. The unit cost of a station installed complete is $5,320. Using that unit cost as a factor, the figures in the first line on page 4 will give the amount of money to be expended under the item "Stations Installed" for each of the years shown. In 1940 the two stations will cost $5,320 each, and in 1942 there will be 12 stations installed at a cost of $63,840. The balance of the line is simply a multiple of $5.320. The units added, of which there will be one in 1942, will each cost complete $4,675. The other amounts set opposite that line are units costing $4,675.

In 1942 we will install an 8,000 gallon lubricating tank, amounting to $1,051, at Skellytown, which is the same Skellytown camp I have already referred to. In 1944 we will install a lubricating oil tank, 8,000 gallon capacity, at an expenditure of $1,051, at the Dumas camp. These tanks are installed for the purpose of purchasing lubricating oil in bulk quantities in order to take advantage of minimum purchase prices, and the oil so purchased will be stored in these tanks.

Under the heading "Book Cost of Property Retired" it is shown that 25 units will be retired in 1952, the book
693 cost of which is $116,875, and under the sub-heading

"Salvage" $99,875 thereof will be salvage. That figure merely represents the book cost of the usable material salvaged.

Cross-Examination by Mr. Slaff Interposed.

Those materials will be reinstalled in the same year at other locations. Those 25 units will make up part of the 37, and 12 additional units will be purchased. The difference between the amount of $99,875 salvage and the $116,875 book cost, comprises such items as labor, transportation, freight, and incidentals. In this case the book cost of the units happens to coincide with the installed price as of June 1, 1939.

Question by the Examiner.

I have been asked to explain how I correlate Item 4 under "Book Cost of Property Retired" and Item 4 under "Additional Capital Expenditures." The book cost of property retired, consisting of the two 12 inch Canadian River lines in the years 1945 and 1947, respectively, is $34,816 in each of those two years; that is, the book cost of the two original lines which were constructed in 1931. That does not refer to the two lines which we are going to construct in 1940. We are not reclaiming those lines in 1945 and 1947.

Direct Examination by Mr. Hedrick.

The reason that the two lines that will be constructed across the Canadian River in 1940 cost so much more than the book cost of the two lines to be retired in 1945 and 1947 is because of the increased cost of material, the increased cost of labor, and the increased cost due to the fact that the overhead and equipment is distributed over a considerably shorter section of line. During the construction of the gathering system one contractor had the entire gathering system, and he was able to distribute all of his overhead expense and his equipment expense over the entire project. In this case, in 1940, it will be necessary for a contractor to bring in men and equipment and organization specifically for a small amount of footage. Also in that figure there is expense for a more substantial design than we had in the lines that were constructed in 1931.

Questions by the Examiner.

These two 12 inch lines are on what we term the Moore County crossing. We do not plan to replace the two lines which we are retiring. The additional capital expenditure item represents somewhat an anticipation of the retirement of those two lines plus whatever operating benefit we gain by putting them in at this time.

Direct Examination by Mr. Hedrick.

The new lines will not be laid at any greater depth than the present line.

694 *Cross-Examination by Mr. Booth Interposed.*

My working papers will not disclose what items have been included in the book cost of the property to be retired. That data must be obtained from the accounting department. That information was furnished to me by the accounting department, and I do not myself know what is included in it. I am not in position to state specifically what is included in the book cost of the items of property retired.

Direct Examination by Mr. Hedrick.

In other words, when I retired the two Canadian River lines I went to the accounting department and was advised by them as to the cost of these two lines that were installed, and I used that figure in my retirement item. That applies with respect to the retirement throughout this exhibit.

Cross-Examination by Mr. Booth Interposed.

I am not able to answer for the accuracy of the book cost items. Those books are in the hands of the accounting department.

Cross-Examination by Mr. Slaff Interposed.

The price as of June 1, 1939, which I used for drips on the 24 inch line is about 100% more than the book cost of the drips which are replaced. When we retire equipment, the equipment is retired at the book cost. The reason that the book cost coincides with the cost for additions as of June 1, 1939, is that there are no additions until on and after June 1, 1939. In other words, there have been no booster stations installed to date outside of an experimental station. Book cost is the original cost of the item.

Direct Examination by Mr. Hedrick.

I now pass to page 5, entitled "Pipeline Department, District No. 2." The first item, "Install Six-Inch Blowoffs," is a pipe connection welded to the top of a 24 inch line and is used for the removal of gas from the line and for the purging of a section of line following a time when the line has been taken out of service for some repair. These blowoffs will be installed at three different locations, one on each side of the main line Canadian River crossing and one on the inlet of the Texoma sales meter near Gray Junction. Each blowoff will cost $346 installed.

I have already stated the necessity for replacing drips in connection with Sheet 3. The necessity for the replacement of these drips is the same as I testified concerning line 5 on page 3. One drip will be replaced in 1940 and one drip in 1941.

The third line is "Replace Headers." The lower picture shown on Exhibit 79, introduced through Mr. Floyd C. Brown, entitled "Typical Manifold for Submerged Pipeline River Crossing," showing a valve assembly and header connection for 24 inch main line, shows the construction of a typical header, which we term a 24 inch by 12 inch six run header. We have headers of different sizes, depending upon the number of multiple lines constructed across a stream. The very short line leading from the left side of that picture is the 24 inch line, and that is connected
695 onto another 24 inch line, out of which emerge six
smaller lines, on each of which is a valve. That is a typical header installation.

As to the necessity for the replacement of the headers in 1940 and 1941, shown on page 5 of Exhibit 105, I have already described in my testimony the effect of corrosion on drips and the fatigue of metal as a result of gusset plate construction. These same factors are applied in the same way in discussing deterioration of headers.

There are additional factors, however, which are working toward the destruction of river headers. There is a continuous pulsation which comes from the operation of the compressor station. That pulsation causes a variation in line pressure, which in turn creates vibration which actually accelerates the fatigue action. The expansion and contraction of the river lines due to temperature changes is dissipated normally in the sinuosity of the lines. At the ends of the river lines, where they are attached to the respective headers, this expansion and contraction due to temperature changes is dissipated in the header, resulting in deformation of the header, which is also contributing toward the physical destruction of that header.

There is another factor which is working on the header, and that is the weight of the gas which passes the header every 24 hours. The approximate weight of this gas is 5,250 tons. I have figured that on 210 million cubic feet per day. At a pressure of 14.65 pounds and a temperature of 60 degrees, 1,000 cubic feet of gas will weigh slightly more than 50 pounds. In my calculations I have used 50 pounds.

The gas as it passes through these headers has a change in direction. In fact, it changes in direction twice, two complete 90 degree changes.

We do not normally think of gas as having weight, and I would like to give one or two examples. This weight is equivalent to a 100 car freight train, each car loaded with 52½ tons of material. Another example is that a stream of automobiles would involve 3,500 cars passing over the header each 24 hours, traveling at the rate of 14 miles per hour. That is only by way of explanation in order to better visualize that there is weight passing through that facility.

The change in direction of this tremendous weight of gas causes part of the vibration in the header.

For the reasons I have enumerated, we plan to replace a header in 1940 at a cost of $2,805 and a header in 1941 at a cost of $2,322. That difference in cost is due to the fact that there is a difference in the design of each of the two headers. The reinforcement of the welds on the headers that were originally installed was the gusset type reinforcement, and on the headers that will replace the present headers the saddle type will be used. On all construction work which we have done since the completion of this line, the saddle type of reinforcement has been used. It was not available at the time of the construction of this pipeline.

One of these headers will be at the main line Canadian
696 River crossing and one at the Moore County check
meter, near Gray, Oklahoma.

Item 4 is "Install 12 Inch Loop Lines," and shows expenditures in 1940 and 1941. A loop line, as I shall use the term, is a pipeline designed to be laid across a stream or an overflow area, or a combination of the two. This line will be laid parallel to the present 24 inch line and will be so installed with gate valve facilities that either of the two lines may be removed from service in the event of failure of one of the lines. 24 inch valves will be installed as block valves in the 24 inch line. Block valves or gate valves are used to stop the flow of gas, to take a section of line out of service.

In the installation of these block valves it is necessary to install a concrete anchor in close proximity to each valve. When a valve is closed with pressure against the closed valve, there develops an enormous total pressure against that closed valve, the amount depending upon the prevailing pressure in the pipeline. For 700 pounds it is in the neighborhood of 300,000 pounds which is tending to push that valve off the line, or rather, it is a thrust rather than a pressure. A thrust is the result of this pressure force.

So that to protect that facility from blowing off the line, so to speak, we install these concrete anchors, which will prevent the movement of the valve when it is in the closed position and a force is acting against it. I am confining myself to Item 4 and am not referring to Item 5.

Questions by the Examiner.

There will be a valve on the loop line itself. For example, for a 12 inch loop line there will be a 12 inch valve installed at each end of this loop line just ahead of the respective connections to the 24 inch line. These loop lines are installed across streams and overflow areas which are susceptible to heavy washing, and those that are inaccessible.

Assuming that we will have a pipe line failure in a 24 inch line with no auxiliary protection in an isolated location, we would have a serious interruption of service, and this is a reinforcement or insurance against the interruption. The loop line construction is a continuation of a program which we have been carrying on. Some of the loop lines that have been heretofore constructed after the original installation are also shown on page 18 of Exhibit 105.

The loop line in 1940 will be constructed at Survey Station No. 605 plus 88. This is a branch of Kit Carson Creek. This survey station is shown on Exhibit 103 on the first line. The second loop line in 1941 will be constructed at Survey Station No. 654 plus 51 and is also indicated on Exhibit 103. These two branches of Kit Carson Creek are unnamed, and that is the reason for designating them by the station number.

Direct Examination by Mr. Hedrick.

In 1940 we have an expenditure of $2,711 for the installation of welding sleeves and concrete anchors. This work will be done at a third branch of Kit Carson Creek at Survey Station 459 plus 78. This work will be done to
697 reinforce the 24 inch line across this creek by making it
more stable and more resistant to the buoyancy of the water under flood conditions. This is also a continuation of work which we have done at various points on the pipe line.

The sixth item is "Lay Six New Lines, Canadian River." I have already testified as to the conditions at Canadian River, and the only additional reason I desire to add is the fact that at the point at which we cross the Canadian River on the main line, the width of the channel is about one-half the width of the channel where the Moore County crossing crosses the Canadian River. This increases the velocity of the water flowing, the depth of the water flowing, and the subsequent increase in force of the moving body of sand.

Those are 12 inch lines. We have six 12 inch lines across that river at the present time, and the six new lines will be laid as a complete new crossing. There are certain improvements that have been made in the construction of river crossings, and these improvements will be incorporated in the construction of the new crossing.

Line 7 is entitled "Cathodic Protection." Cathodic protection has been previously described and will be used in District 2 for the protection of the 24 inch main line. Approximately two miles are involved in each of the two years.

The book cost of the property retired and the salvage are shown at the bottom of page 5.

Question by the Examiner.

The plan is to lay three of these new lines across the Canadian River in each year. The reason for that is that we are limited as to the time during the year in which construction can proceed.

Direct Examination by Mr. Hedrick.

One of the counsel asked me a question with reference to the book cost of property retired on page 3 of Exhibit 105, being Item 4, "Retire Two 12 Inch Canadian River Lines," and inquired whether or not I had a breakdown of the retirement of $34,816 set out in each of the years 1945 and 1947. I told him I did not, but that I would get that information from the accounting department. I wish to make a statement with reference to that.

After having time to review my detail sheets, I found that I had those items shown under 1945 and 1947 in detail in one of my work books for the retirement of two 12 inch Canadian River lines, and I will be glad to review the details with counsel.

Page 6 of Exhibit 105 is entitled "Pipeline Department. Additional Capital Expenditures and Book Cost of Property Retired—Tools." The replacement of equipment to which I will subsequently refer will be done from time to
time. The reason for these replacements is due to the
698 fact that by continued use the equipment is wearing
out and deteriorating to the point where it is no longer advisable to continue its use at the time the replacement takes place.

We are also going to purchase additional equipment. The reason for that is that as the property becomes older there is more work of a remedial nature to perform, which will require the added equipment in connection with those repairs. There will be more maintenance to be performed in the future than there has been in the past because any structure that gets older with age requires more maintenance to keep it in operation. This pipe line structure is practically all a sub-surface structure, and, in addition to the normal wear and tear of the structure, it is subject to the destructive forces of corrosion.

~~The~~ first item is "Melting Kettles." These kettles are used for the heating and melting of the pipe coating material known as enamel, which is applied to the pipe and other sub-surface structures for the prevention of corrosion. In 1941 we will replace two kettles, both of which were purchased originally in 1931.

Item 2 is a 3P Jaeger centrifugal pump. This pump, along with the following pumps which will be referred to, is used for dewatering trenches, bell holes, or at any point where it is necessary to move water before repairs or remedial work can be done. A bell hole is a large opening excavated around the pipe to permit one or more workmen to perform their duty in connection with making repairs. In 1943 we will replace a Jaeger which was purchased in 1935. These are all portable pumps. The Jaeger pump is a gasoline engine driven pump. The bell holes I refer to are similar to the bell holes which were dug, to the extent of 100 or more, when Mr. Biddison, accompanied by Mr. Johannigsmeir of the Federal Power Commission, inspected the pipeline for visible depreciation a short time ago. They are the same type of excavation.

The next item is electric welding machines. Those are gas engine driven direct connected generators, used for the application of the electric arc in making what is called an electric weld. In 1942 we will purchase an additional machine. In 1943 we replace the machine which was purchased in 1937. In 1948 we replace the machine which was purchased in 1942. In 1949 we replace the machine that was purchased in 1943.

I notice I have overlooked two melting kettles and a Jaeger pump in 1951. In 1951 the melting kettles will be replaced which were purchased in 1941 and the Jaeger pump will be replaced in 1951 which was purchased in 1943.

The next item is a 4-inch Rex pump. This is a gas engine driven centrifugal pump. 40-M means the capacity is 40,000 gallons per hour. It could be used for oil, but we use it for water. In 1946 we will replace the pump that was purchased in 1938.

The next item is a 6-inch Rex pump of the same type,
699 except a larger capacity pump. It is a 90,000 gallon
per hour pump. It was purchased in 1938 and will be
replaced in 1946.

The next item is a rotary scraper. A rotary scraper is a piece of equipment similar to the Fresno, which we see used in construction jobs, road construction, railroad construction, or any excavation jobs. Practically the only difference between the rotary scraper and the Fresno is that the bucket can make a complete revolution when emptying the material from the scraper. These scrapers are used in connection with trucks, principally with tractors. This rotary scraper will be replaced in 1946. It was purchased in 1938.

Cross-Examination by Mr. Slaff Interposed.

According to the exhibit, a Jaeger centrifugal pump is to be installed or bought in 1951 to replace the 1943 pump. Counsel has inquired why the book cost of property retired, 3P Jaeger centrifugal pump in 1951, is $296 instead of $310, which was the book cost of that property in 1943. Apparently that is an error. It should be $310, just roughly checking it here now. The original pump that we purchased in 1931 will be replaced in 1943 and the book value or book cost of that pump was $296, and apparently an error exists by simply using that same figure for the pump that will be purchased in 1943. To be exact, it should be $310 under the year 1951.

Direct Examination by Mr. Hedrick.

The next item, a rotary scraper, is the same type of scraper but of heavier design, for a larger tractor, and will be purchased new in 1943. The purpose of that is to handle heavier excavations and more excavations as the property becomes older.

The next item is electric lighting units. These are gas engine driven direct connected generators generating 110 volts. They are used for the operation of the company's radio equipment and to furnish light for men working during emergencies or at night about the property. They are small portable units. The unit which was purchased in 1938 will be replaced in 1948.

I referred to radio equipment. We have equipped the north end of the pipeline system with portable telephone-radio equipment. We have transmitting and receiving stations at Station 6, Red Oak, Iowa, and at Stations 8, 9 and 10. We have receiving sets installed on trucks, superintendents' and foremen's automobile equipment.

This radio equipment was purchased primarily to facilitate the repair of this pipeline during emergencies, from a communication standpoint. We have found, and it has been our experience, that our pipeline breaks occur as the result of some natural force over which we have no control.

During those same periods communication systems are out of order. I am referring to floods, sleet, hail and tornado. The farm systems are not always adequate and are not reliable. Based on the experience we have had, we decided to use the radio equipment.

700. We have used this equipment several times since its installation in connection with shutouts and repair work that we have done on the line from time to time. In fact, last Sunday we had the line shut out at Grand River, which is in western Iowa, in District 5-W. This line was shut out for the installation of 24 inch gates and 12 inch gates for the connection of a 12 inch loop line which is just being completed. We have no company telephone communication in close proximity to that work. The telephone lines of the company do not follow exactly where the pipeline is across Iowa and Illinois. In Kansas they do not parallel the pipeline in a diagonal route. They do follow the section line roads, but zigzag across the pipeline across Kansas and Nebraska as far as Beatrice. At Beatrice, Nebraska, the telephone line is constructed on the Burlington Railroad right of way poles and from that point to Chicago the service is on the Burlington right of way.

During a shutout it is necessary for the dispatcher in the Chicago office to keep in close contact with the progress of the work. Obviously he is interested in when he will be able to return the pipeline to service for the continuation of the delivery of gas. The radio equipment is used to contact our stations on either side of the work, in order to keep them advised as to the progress of the work, to direct the activities of the men, and, if need be, to order additional material that may be required.

Question by the Examiner.

I said the farm systems are not so reliable. There are a number of telephone systems in the country that are not owned or controlled by the Bell Telephone Company, A. T. & T., or any of its subsidiaries. A group of farmers will combine and construct a telephone line in some local area for their own use. Those systems are usually constructed on very meager poles. Sometimes they follow the fence poles, and sometimes they are secured to trees along the fence line. They are not adequately maintained and they are subject to the elements or destruction more readily than the regular commercial lines.

We sometimes use those in getting a connection with the Bell system or our own system.

The next item is a one-half yard power shovel, dragline and pull shovel. This equipment is similar to the steam shovel type, except that it is gasoline engine powered. It is equipped so that a dragline can be used or a pull shovel can be used, depending upon the nature of the work to be performed. We are going to purchase this equipment in 1943 in order to handle the heavier excavations and remedial work on the pipeline that we will have to do in the ensuing years.

The next item is that of air compressor and tools. In 1946 we will replace an air compressor and auxiliary tools which were purchased in 1938. The air compressors are used for various purposes, such as rock excavation, 701 hard soil excavation, operating pneumatic tools, pneumatic motors and for excavating frozen ground.

The next item is a C. H. & E. diaphragm pump. C. H. & E. is just an abbreviation of the name of the company from which we purchased the pump. I don't have the name of that company here. It is a gasoline driven pump. We purchased that pump in 1937 and it will be replaced in 1945.

The next item is Goulds diaphragm pump, which is the same type of pump as the preceding one, and is hand operated. It will be replaced in 1944.

The next item, snow plow for trucks and caterpillar tractors, shows an expenditure in 1942 of $600 for snow plow equipment for a truck and a tractor. This equipment will be used for keeping the roads open in the gathering system so that the chart changers and men responsible for the operation of the booster stations will be able to carry on their duties in the gathering system. In 1943 we will purchase a snow plow for the tractor which is to be purchased also in the same year.

The snow plow is used for the removal of snow from the roads which exist through the gathering system. These roads have to be cleared to permit chart changers and maintenance men to cover their duties in the gathering system in connection with changing charts and maintaining and operating the booster stations in connection with the flow of gas. We haven't purchased the snow plows before because we haven't had satisfactory equipment on hand to use as a motive power for the snow plows. They can be used to some extent with trucks, but not satisfactorily. We did not have the caterpillars until 1938.

The next item is a bull dozer for an R-4 caterpillar tractor. A bull dozer is a piece of equipment for back filling an excavation. It is mounted on the front end of a tractor and is used to push the soil or excavated dirt into the trench.

The next item is an acetylene generator. This is used for the generation of acetylene gas used in the acetylene welding process. Such a generator was purchased in 1935 and will be replaced in 1943.

Item 16 is for small tools, additions and replacements. We have a number of smaller pieces of equipment and tools costing in excess of $25 which are not detailed on page 6. $500 per year is to be used for the purchase of small tools as they become worn out and of no further use, and for the purchase of additional small tools as and when they may be required.

The book cost of the property retired and the salvage are also shown on page 6.

The four-inch and six-inch Rex pumps which we now have were bought in 1938.

702 Page 7 is entitled "Natural Gas Pipeline Company of America, Pipeline Department, Summary of Capital Expenditures and Book Cost of Property Retired." Under "Additional Capital Expenditures" Lines 1 to 8, entitled "District No. 3," "District No. 4," "District No. 5-W," "District No. 5-E," "District No. 6," "Branch Lines," "Joliet Meter and Regulator Stations," and "Tool Account," are shown more in detail on pages 8, 9, 10, 12, 13, 14, 15, and 16, respectively. Under the heading "Book Cost of Property Retired" Lines Nos. 10 to 17, inclusive, are set out more in detail on pages 8, 9, 10, 12, 13, 14, 15, and 17, respectively. Under the heading "Salvage" Lines 19 to 26, inclusive, are explained more in detail on pages 8, 9, 11, 12, 13, 14, 15, and 17, respectively.

Turning to page 8, I have already explained what a drip is and also what a river header is. I have no additional reasons for replacing drips to add to those which have been previously stated. For the years 1940 to 1945, inclusive, there will be one drip replaced in each year. I have no further information regarding river headers with respect to reasons for replacements.

The item of $3,418 in 1940 is for the replacement of two 18 by 12 inch headers. In 1941 the expenditure is for the replacement of one 24 inch by 12 inch header, which is a six-run header. In 1942 it is for two 18 by 12 inch headers. In 1943 the amount is for the replacement of one 24 by 12 inch header. In 1944 the amount is for the replacement of two 24 by 18 inch headers. In 1945 the amount shown is for the replacement of one 24 by 16 inch header, which is a three-run header. In 1946 the amount shown is for the replacement of one 24 by 12 inch header and one 24 by 18 inch header.

With reference to Item 3 I have already explained what 6 inch blowoffs are. This item includes a number of 6 inch blowoffs represented by expenditures in the years 1939 to 1943, inclusive. The installation of a 6 inch blowoff costs $346. In 1939 four of these blowoffs will be installed; also the same number in 1940, 1941 and 1942. In 1943 there will be three 6 inch blowoffs installed.

Item 4 is "Install Two 16 Inch Lines, Beaver River," with an expenditure of $120,207 in 1941. Beaver River is located on Exhibit 103, and it is the third river named on the last horizontal line, third from the lefthand side of the exhibit. The crossing is located in Beaver County, Oklahoma, near the town of Beaver. This river is crossed at the present time with six 12 inch pipelines and one 16 inch line. On the north side of the river the six 12 inch lines are divided into two groups of three lines each. An 18 inch line connects each of these two groups of three 12 inch lines to the 24 inch main line through a 24 by 18 inch header.

Beaver River at the point of the pipeline crossing has a flood bottom from bank to bank of about 4,000 feet. That is not from bank to bank of the channel; it is from bank to bank of the entire flood area, the overflow area. This flood bottom during the first years of operation was well covered with vegetation. It was a meadow or
703 pasture. During the drouth years practically all of this
vegetation was destroyed. Floods which occurred deposited sand on these flood bottoms, which further destroyed the remaining vegetation. The wind erosion and lack of water during this two or three year period resulted in the wind actually filling the main channel with dry sand. The flow was all sub-surface. Following that, when floods occurred, the channel overflowed the surrounding flood plain, due to the fact that the elevation of the bottom of the channel was at that time higher than many portions of the adjacent flood plain.

In 1937 we experienced a series of floods in that river, which formed a new channel to the north of the channel which existed at the time we constructed the pipeline. These floods also formed a new channel south of the old channel, and near or adjacent to the south bank. This cutting and erosion action resulting from the floods and the formation of new channels undermined the six 12 inch pipelines, which left them completely exposed to the forces of the river. As an emergency measure, in July, 1937, we lowered sections of the 12 inch lines at a cost of $22,000. That expenditure is shown on page 18 of this exhibit.

Major operations of that character are performed by our own personnel. We supplement our regular forces by the employment of additional men. That is with reference to the type of work which I described on Beaver River, which is more of an emergency character. In the construction of pipelines, loop lines, or the extension of lines, where we have time to design and plan the work, those lines are practically always contracted for.

After this experience on Beaver River we were firmly convinced of the necessity of providing some adequate protection and insurance for continuity of service at that stream. We designed and prepared specifications and secured contracts for the construction of a 16 inch pipeline to be laid entirely across the overflow area at a depth varying from ten to twelve or fourteen feet below the normal surface of the overflow area and the stream beds at that time. This work was completed in 1937.

That is shown on page 18 of this Exhibit 105 under District 3, the third item under that district, for work which was performed in 1937 at an expenditure of $69,698.29. At the time that line was constructed we installed header facilities for the installation of two additional pipelines, having in mind at that time that at some future date we would install two additional 16 inch pipelines.

We have recently experienced another flood of the Beaver River which again formed a new channel north of the north channel, which was formed in 1937. This new channel is gradually approaching the north two 18 inch by 12 inch headers. We are at the present time making an emergency expenditure to protect those lines from forces that will develop in this new channel.

In 1941 we have an amount to be expended for the in-

stallation of two 16 inch lines which were contemplated
704 in 1937. If the flood conditions on Beaver River continue, we may be forced to spend that money at an earlier date.

As to whether a bridge would be practical at this Beaver River crossing, a bridge of the suspension type to be constructed at that location would require a clear span of at least 4,000 feet. We have not as yet seen a design for a suspension type bridge having a clear span of that distance that is satisfactory or acceptable to us for the carrying of a pipeline suspended across the entire flood area.

The next item is "Install 12 Inch Loop—Crooked Creek." Crooked Creek is shown on Exhibit 103, on the first pink horizontal line. The crossing is located south and a little west of Meade, Kansas, in Meade County. The creek at the present time is crossed with a single 24 inch pipeline. This creek is subject to overflow periods of as much as a week. A failure in the 24 inch line during one of these flood periods would result in considerable interruption of continuity of service. We have designed a 12 inch loop line to be constructed parallel to and connected to the present 24 inch line. This loop line will be 2,000 feet in length. The expenditure will be made in 1942, amounting to $28,444.

Item 6 is entitled "Install 15,600 feet—12 inch Extension—Arkansas River." The Arkansas River is crossed with six 12 inch lines, that is, the main channel. The overflow area to the south is crossed with two 18 inch lines, and the overflow area to the north is crossed with two 18 inch lines. This river is located east of Dodge City, Kansas, and is shown on Exhibit 103.

This river is a characteristic stream of the streams in Kansas and in Oklahoma and Texas. That is, the stream bed consists of sand and the overflow area consists largely of sand. Whe are going to be required to recondition the six 12 inch lines across the Arkansas River. During this operation, or at the time the lines are reconditioned, they will be lowered a depth of six to eight feet and the river headers on each side of the river will be extended back by extending the six 12 inch lines.

This river is attempting to widen its present channel, following the same general action that has taken place on Beaver River which I have just described. It is for the protection of this crossing against any interruption of service that we are going to extend the 12 inch lines and lower the 12 inch lines in 1943, at a cost of $139,227.

As to whether we now have any river work in progress such as I have testified about on Lines 4, 5 and 6, we have river work going on at the present time. We are lowering the 12 inch lines at the Republican River, on the south side of the Republican River, near Concordia, Kansas, in Cloud County. We are lowering the two 18 inch lines and extending the east 18 inch by 24 inch header on the east side of the Nishnabotna River.

We are constructing a 12 inch loop line at the Grand 705 River crossing in central western Iowa. You will find that name on the top horizontal line of Exhibit 104. We are lowering the six 12 inch lines across the Des Moines River in the central part of Iowa, near Tracy, Iowa. That covers the river work which is in progress as of the present time.

Item 7 is entitled "Raise Three-Inch Blowoffs." The three inch blowoff is the same type of facility as described for the six inch blowoff, except that it is a smaller size. They are installed on each end of each river line and are used for the purpose of removing gas from the river lines. These blowoffs are being raised. At the present time the piping and gate valve are below the elevation of the ground surface. The expenditure under 1939 involves 128 blowoffs, and that work is now in progress.

Item 8 is entitled "Install Gate Boxes." A gate box is a small galvanized corrugated iron building constructed on a steel framework and is used to completely house a main line valve or river valves at a river header. They are installed for the purpose of facilitating the operation of these valves during emergencies, to facilitate the servicing of the valves from the standpoint of lubrication, packing the stuffing boxes, and to protect the valves from the elements, such as ice, snow, sleet, and so on. That work is now in progress.

Questions by the Examiner.

These valves have not been housed in the past. We plan ultimately to house every valve. This program is a continuation of a program that has been going on for the past five or six years. We have all of the valves housed on the north end of the system, as shown on Exhibit 104.

I mean by that, all in Districts Nos. 5-W, 5-E, and 6. The expenditure in 1939 is to be made and is being made for the installation of gate boxes at the Cimarron River crossing, the Arkansas River crossing, the Saline River clossing, Willow Creek, Pawnee, Smoky Hill River, Beaver River, Walnut Creek, and Salt River.

Direct Examination by Mr. Hedrick.

Item 9 is entitled "Install Cathodic Protection," and I have already described what it is. The expenditure for 1939, in the amount of $5,154, is now in progress; that is, the work is in progress. That is for the cathodic protection of five miles of 24 inch line in the vicinity of Wilson, Kansas. We have additional sections of 24 inch pipe between the Smoky Hill River crossing and the Pawnee River crossing which will also be protected with cathodic protection in the years 1941 and 1942, respectively. There will be approximately four miles of line to be protected in each of those years.

The book cost of the property retired and the salvage are shown at the bottom of page 8.

Cross-Examination by Mr. Slaff Interposed.

The swage drains which I said were to be retired
706 are handled under maintenance expense and they are included in the operation and maintenance figures. They are originally in capital. The accounting department has a rule that when the item of investment is very small they do not consider it necessary to go through the mechanics of removing the items such as those swage drains from capital investment. The swage drain is all junk material.

As those swage drains are taken out of the plant and service, nothing is removed from the capital cost on account of those removals from plant, except that I should say that this pipe that is installed to replace the swage drain is, in a sense, a capital expenditure. In fact, such capital expenditure is more than the capital expenditure of the initial cost of the swage drain. The difference between the two items is comparatively small, and we do not make a charge and credit for capital as we do in items of considerably larger amounts. The pipe that replaces the swage drain represents an amount approximately equal to or more than the cost of the swage drain. The cost of the pipe which replaces the swage drain becomes part of the capital structure, because without that pipe the line would not be a whole pipeline.

The accounting of that cost is handled as a maintenance item. If we were to complete the details of that transaction it would mean that we would wind up with more capital investment on the books than we had originally with the swage drain, but the item is so small from the standpoint of money that the accounting department does not think it advisable to use the necessary routine mechanics in transferring that transaction.

Direct Examination by Mr. Hedrick.

Page 9 is entitled "Pipe Line Department, District No. 4; Additional Capital Expenditures," etc.

The first item, "Replace Drips," is for the replacement of one drip in each of the years 1940 to 1943, inclusive, showing an expenditure of $1,468 for each year.

The next item is one of replacing river headers. In 1940 one 18 inch by 10 inch header will be replaced. In 1942 one 24 by 18 inch header will be replaced. In 1942 one 24 by 12 inch header will be replaced. In 1943 one 18 by 12 inch header will be replaced. In 1944 one 24 by 16 inch three-run header will be replaced; and in 1945 one 16 by 12 inch header will be replaced. In 1946 a 24 by 12 inch header will be replaced.

The third item is "Install Gate Boxes." That work is now in progress.

The next item is to install 6 inch blowoff connections in the years 1940, 1941 and 1942. The amounts shown are for the installation of three 6 inch blowoffs in each of the years.

Item 5 is "Install 18 Inch Loop, Weeping Water
707 Creek." Weeping Water Creek is located just southwest of the Missouri River crossing, approximately
15 miles from there. It is crossed at the present time
with a single 24 inch pipeline, and for the same reasons
which have been explained for the installation of loop
lines, we will install an 18 inch loop line at this location
in 1942, involving an expenditure of $36,591.

Item 6 is "Raise 3 Inch Blowoffs." 47 three inch blowoffs will be raised in 1940 at a cost of $1,034.

Item 7 is "Install River Clamps, Reinforcing Straps, Republican River," requiring an expenditure in 1939 of $11,658. That work is now in progress.

Item 8 is "Cathodic Protection," requiring an expenditure in 1941 of $3,969 and in 1942 of $3,970. We are going to protect approximately three and eight-tenths miles of 24 inch line in each of those two years.

Item 9 is "Install River Clamps and Reinforcing Straps, Little Blue River," with an expenditure in 1941 of $21,315.

The Little Blue River is crossed with six 12 inch pipelines and is shown on Exhibit 103. It is the first multiple line crossing northeast of the Kansas-Nebraska state line. The reasons for this expenditure are that the river is changing its channel. The river is attempting to return to its former channel, which is north of the present channel. There is also a possibility that a new channel will be formed south of the present channel. These 12 inch lines will be lowered and reconstructed in 1941 for the purpose of reconditioning the lines and lowering them to a depth of six to eight feet below the present stream bed as a protection against washing when these new channels are formed. This work will be done at an expenditure of $21,315.

A reinforcing strap is a metal bar made of mild steel one-half inch thick by two inches by ten inches long. These bars are welded across the girth weld and are spaced 90 degrees apart; that is, there are four reinforcing straps for each girth weld. That is to strengthen the tensile strength of the girth weld. I should explain in connection with this item at the Little Blue River that this expenditure in 1941 is for the additional capital expenditure which will be required; that is, the additional clamps which will be installed and the additional reinforcing straps which will be installed.

The book cost of property retired and salvage are shown at the bottom of the page.

Under "Book Cost of Property Retired," Line 1 is "Retire Drips, 17-18-19-20." Those are the numbers by which the drips are referred to from an operating standpoint and are shown on Exhibit 103 in the horizontal line entitled "Drips."

708 *Cross-Examination by Mr. Slaff Interposed.*

The book cost of No. 17 of the drips appears to be about 35% more than the book cost of Nos. 18, 19 and 20. Drip No. 17 is on the discharge side of Station No. 5, and was not installed by the same contractor that installed the remaining drips. The difference is the difference in contract labor. The additional expenditure for drips Nos. 17, 18, 19 and 20 will be the same. That is an expenditure to be made by our own company personnel and we can control those expenditures. The contract labor, of course, is submitted by the contractor in his proposal for the performance of that kind of work. There is no physical difference in the type of construction or anything of that sort that would explain the difference in price. That does explain the difference in the cost of many items. In this particular case it was the difference in the unit cost the contractors submitted.

Direct Examination by Mr. Hedrick.

It is suggested that there may be some confusion with reference to the names Little Blue River and Big Blue River. The river I am testifying about on page 9 of Exhibit 105 is called Little Blue River and is located in District No. 4 in the southern part of Nebraska, and Item 9 on page 9 crosses that river. I have heretofore testified concerning a Big Blue River, and that river is located in Moore County, Texas, and is crossed by the main trunk gathering line of Texoma Natural Gas Company.

We have heretofore constructed a suspension bridge across the Big Blue River in Moore County, about which I have testified, and I have also testified that we will in the future construct another suspension type bridge across Big Blue River, which is designated on Exhibit 101 as Big Blue Creek, in lieu of the under-river 24 inch line that is there at this time. We also cross with a main trunk gathering line the Big Blue River in Moore County, Texas, at another point, but we do not contemplate any remedial work at that place.

Turning now to page 10 of Exhibit 105, I will explain Items 1 to 21, inclusive, on that page.

The first item is "Replace Drips." We will replace one drip in each of the three years, 1940, 1941 and 1942, at a cost of $1,468 in each year.

The second item is "Replace River Headers." In 1940 we will replace one 24 by 18 inch header; in 1941, one 18 by 10 inch header; in 1942, one 24 by 18 inch header; in 1943, one 24 by 18 inch header; and in 1944, one 24 by 18 inch header.

The third item is "Replace 24 Inch Line—Walnut Creek." Walnut Creek is a stream crossed with a 24 inch pipeline. It is located three and one-half miles west of the company's Red Oak meter setting. There are two reasons for the work to be done at this creek,
709 one of which is corrosion, and the second being to
lower the 24 inch line below the scouring gradient of the creek.

By reference to page 18, Exhibit 105, under District No. 5-W, it will be observed that we have been performing work of this nature since 1935. A large number of these rivers and creeks in Iowa have been straightened. The farmers will form a drainage district and combine their resources and straighten a section of a stream for the purpose of increasing the run-off, reducing flood conditions, and increasing the acreage of their fertile land. When a meandering stream is straightened, the velocity of the water increases. This increased velocity causes scouring of the stream bed. It is endeavoring to approach a normal gradient of flow. Our experience has been that this scouring has scoured to depths below the depth of the pipeline, which leaves the pipeline exposed to debris and ice jams and the forces of flood waters. We have had to do considerable of this kind of work in Iowa and Illinois, due to the straightening of channels and the scouring of the stream beds.

At Walnut Creek it is our judgment that this crossing should be reconditioned. It is not practical to recondition a 24 inch pipe while in service across a stream. We depend entirely for the stability of the 24 inch line on the back fill and on the soil adjacent to the sides of the pipeline and at the bottom of the pipeline. If soil or back fill are removed from this 24 inch line, it is subject to floating during flood conditions, and at vertical bends there is a resultant component of force, caused by the internal pressure of the line, which has a tendency to lift the pipe at that point.

To do the work desired, we are going to lay a new section of 24 inch line approximately 300 feet long. This new line will be laid across the stream at a depth of six to eight feet below the present stream bed. That depth to which I refer will depend entirely upon our survey of the stream at the time or prior to the execution of the work.

After this line has been constructed we will have a shut-out and connect the new line to the existing 24 inch line. The old line that is now across the stream will be removed from service. This work at Walnut Creek will be done in 1940, at an expenditure of $8,833.

The next item is "Replace 24 Inch Line—Middle Nodaway River." The Middle Nodaway River crossing is ten and one-half miles east of the Red Oak meter station, as shown on Exhibit 104. This stream is now crossed with a single 24 inch line. We are going to construct a new 24 inch section of line in 1941 at an expenditure of $8,833, which will be a section 300 feet long. 300 feet is about the minimum we can practically handle when replacing a section of line of this character.

The next item is "Replace 24 Inch Line—South River."
South River is three miles east of compressor station No.
8, and in this connection I will refer you to "Replace 24
Inch Line—Box Elder Creek," in Line 20. Box Elder
710 Creek is due west of South River and is a tributary to
South River. My explanation of one would apply alike
to the other, and the reasons for replacing the 24 inch line
at each of these points will be the same as those I have already mentioned.

In 1942 we will replace the single 24 inch line at the South River at a cost of $8,833, and also the 24 inch line at Box Elder Creek.

I stated that the Middle Nodaway River is ten and a half miles east of the Red Oak meter station. I should have said that it is located three miles west of main line gate No. 55, as indicated on Exhibit 104. It is the West Nodaway River which is located ten and a half miles east of our Red Oak meter station.

The reasons for constructing a loop line at the latter location are the same as have been given in connection with other loop lines. We will construct this loop line in 1940 at a cost of $26,362.

The seventh item is a 12 inch loop 1980 feet long. The overflow area is 1815 feet across the South River. We have flood periods of six to eight days at Box Elder Creek.

The latter is a tributary of South River and whatever condition there is on one stream will affect the other.

In 1941 we will construct a 12 inch loop line at South River at a cost of $24,703. Box Elder Creek has an overflow area of 3215 feet.

Item 8 provides for a 12 inch loop across this creek and overflow area a distance of 3415 feet at a cost of $35,523.

Squaw Creek is crossed with a single 24 inch line and is located 8½ miles east of compressor station No. 8, as shown on Exhibit 104. The overflow area at this point is 3500 feet. Item 9 provides for a proposed loop line 3650 feet long to be constructed in 1942 at an expenditure of $37,295.

At Otter Creek, located two miles east of main line gate No. 61, which is now crossed by a single 24 inch line, a loop line will be added in 1942 at a cost of $19,652. This is Item 10.

The overflow area of that creek is 1100 feet. The loop line will be 1310 feet long. With one exception all of these loops in 5-W are 12 inch loops.

Item 11 refers to 115 coupling sleeves. We have a number of locations along the pipeline in western Iowa where the 24 inch line crosses small streams with varying amounts of overflow area. At some of these points we cannot justify loop line construction, but we are going to reinforce the line and provide more stability by installing sleeves around the 24 inch couplings.

The picture in the lower lefthand corner of Exhibit 106 entitled "Split Steel Welding Sleeve Installed on 24 Inch
Coupling" shows a steel forging made in two halves.
711 It is swaged out to accommodate and provide clearance
for the 24 inch coupling. This coupling is installed at a place where the joints are coupled and not welded. The 24 inch sleeve is welded at each end circumferentially to the 24 inch pipe. There are two longitudinal welds but these cannot be seen in the picture since they are at the 90 degree point from the top center of the pipe. Our first sleeve installation was made in 1932. We started to develop the design for this sleeve at that time. It was designed so that it can be installed on the pipeline under full operating pressure conditions. This enables us to do considerable remedial work on couplings without removing the pipeline from service.

(EXHIBIT 106 was offered and received in evidence without objection.)

These 115 coupling sleeves will be installed in 1939. The work has been approved by the management and the actual physical work will be done as soon as weather conditions permit.

Item 12 provides for the installation of 6 inch blowoffs. We will install two blowoffs in each of the years 1939 and 1940; three will be installed in each of the years 1941, 1942 and 1943; and in 1944 two blowoffs will be installed.

Item 13 refers to the replacement of 5,000 feet of 24 inch pipe at Keg Creek, which is located just south and west of Glenwood, Iowa.

(A document containing two pictures, one numbered 20-3, entitled "Showing Location of 24 Inch Line Along CB&Q Tracks West of Keg Creek," and the other numbered 20-4, entitled "Keg Creek, Looking Upstream from South Bank. Rock in Stream Shows Location of Pipeline," was produced by counsel, and at the direction of the Examiner it was marked Exhibit 109 for identification.)

At the time the 24 inch main line was constructed east from the Missouri River in western Iowa in 1931, we were not able to secure rights of way for the projection of a straight line over the farm property shown in the top picture of Exhibit 109, No. 20-3. It is that small cleared area just to the left of the righthand edge of the picture approximately 1¼ inches from the bottom of the picture. The land in the lower righthand corner is not the land to which I referred. It is the land as indicated by a horizontal line which is above what seems to be some rough vegetation. It is approximately directly opposite and on a horizontal line from the two flags shown on the picture.

We were fortunate in securing a right of way, however, from the Burlington Railroad, which permitted us to construct the 24 inch line along and on their right of way. The 24 inch line leaves the private right of way at the fence line indicated by the fence posts in the lower righthand corner of the picture. It enters the railroad property at the point indicated by the white flags. It proceeds down
the railroad right of way to the right of the adjacent
712 track to a point beyond the semaphore. It continues
further along the right of way between the opening in the trees about the middle of the picture from top to bottom. It is to the right of the horizontal center of the picture. Immediately after the pipeline enters that point where the opening in the trees exists, it makes a bend to the right, or south, and crosses Keg Creek. This creek is shown in the picture at the bottom of Exhibit 109. It flows

toward the lower lefthand corner in a general northeasterly to southwesterly direction. A rock will be noted at the point where the 24 inch line crosses this creek. Within two or three hundred feet after crossing this creek the pipeline returns to what was the original projected line.

The owner of the property across which we were at first unable to obtain a right of way has passed away within the last year or two and we have now ascertained that we can purchase a private right of way across this particular section of land. A hazard exists in having a pipeline parallel to and on the railroad right of way. In the event of a railroad wreck at that location, serious damage to the 24 inch line might result. Conversely, if the pipeline should have a failure at any point along the railroad right of way it would imperil the railroad property as well as life.

It will be necessary to recondition the 24 inch line across Keg Creek and for that reason it will be necessary to construct a new section of line. It is our judgment that the 24 inch line should be removed from its present location along the railroad right of way and relaid on a private right of way, with a new crossing at Keg Creek.

It will be noted in the picture in the lower part of the page of Exhibit 109 that the rock protection which we have placed in the stream is an obstruction to the stream flow. It can be observed that the gradient of the stream, both below and above the crossing, is lower than at the crossing. If this rock protection should be washed out by flood the results would be serious to the single 24 inch pipeline. The stream was straightened out about five years ago and scouring has been taking place since that date. We are going to reconstruct this section of 24 inch line, 5,000 feet in length, in 1942, at a cost of $58,696.

The railroad is shown to the left of what appears to be the spoil bank, or what remains of an old levee, on the left side of the bottom picture on Exhibit 109. There is a short overflow area in the immediate vicinity of the Keg Creek crossing. This overflow area is not shown on the picture but would appear at the right if the picture were extended.

(EXHIBIT 109 was offered and received in evidence without objection.)

Cross-Examination Interposed by Mr. Slaff.

The physical conditions under which the 24 inch line is to be replaced at Keg Creek are practically the same as those at Walnut Creek.

You ask why the large difference in the unit price
713 per foot of pipe in the case of the two installations.

The line to be reconstructed at Walnut Creek involves a section 300 feet long. At Keg Creek we are constructing a line 5,000 feet long, approximately a mile. The unit costs of the latter will therefore be less, due to the additional footage involved in the project. The reason for this is that we will have practically the same amount of equipment to reconstruct the Walnut Creek crossing as will be required to construct the new section of line across Keg Creek and to the west. The overhead cost of the moving in and out of equipment, equipment rentals, personnel, overhead, and office rent will all be spread against 5,000 instead of 300 feet. Both items will be built by contract.

The same explanation would apply to the replacement of 300 feet in the Middle Nodaway River and the replacement of 300 feet at the South River. The replacement at Box Elder Creek is also of 300 feet, and the same explanation applies there.

Direct Examination by Mr. Hedrick.

If we were laying 300 feet across Walnut Creek and 300 feet across Keg Creek, the cost of that work would be almost the same. As I recall these two stream crossings, Keg Creek would be more expensive than Walnut because of the depth of the stream, which can be observed from the picture. The laying of the greatest percentage of the 5,000 feet will be west of Keg Creek and will be what we term nominal construction, which also tends to decrease that overall unit cost.

I will now pass to Item 14. The Missouri River is crossed at a point south of Plattsmouth, Nebraska, as shown on Exhibit 103. The channel is crossed with 10 inch pipelines. At the time of construction we considered the Missouri River to be the most treacherous stream with which we had to deal. At that time we did not consider the Canadian River as serious a stream as the Missouri. We have changed our minds since that time. We designed a 10 inch crossing across the Missouri for the reason that we did consider it a very treacherous stream. We based our judgment on our past experience in constructing pipelines across the Missouri River, as Mr. Floyd C. Brown has testified.

The characteristic of the Missouri River is to shift in its channel course. It is known to shift in its stream bed. There will be much shifting of sand bars. The same factors are working on this crossing which we enumerated for the lines in the Canadian River, namely, fatigue, corrosion, structural weakness, and the natural forces of the stream as a result of floods and ice jams.

We have no way of determining the amount of corrosion that exists on the Missouri River lines. In order to reinforce this crossing and provide the insurance that is required for continuity of service, we are going to construct four new 10 inch lines in the years 1943, 1944, 1945 and 1946, as shown here, at an expenditure of $54,158 in each of the four years. One line will be constructed each year.

We are limited in this construction program on account of weather conditions and the drainage situation at
714 the Missouri River. This is a safety measure and we
cannot afford to take any chances on losing this river crossing. The physical work on the Missouri River crossing was started in the fall of 1930 and it was not completed until some time in the summer of 1931. The work was completely shut down during the winter months on account of ice in the river. If we should lose the Missouri River crossing, in my judgment it would take not less than thirty days, and more likely sixty days, to complete a satisfactory crossing for the resumption of service.

The 18 inch loop line, Missouri River to Horse Creek, referred to in Item 15 is to be constructed from the east 18 inch by 24 inch header at the Missouri River on to Horse Creek. Beginning at said Missouri River header, there exists approximately a mile and a half of overflow land. During flood periods water accumulates in this area and the only outlet is by evaporation or seepage.

We have a serious condition at Mays Creek, which is located approximately three-eighths of a mile east of Keg Creek, and also at Horse Creek, about one and one-third miles east of Mays Creek. The 18 inch proposed loop line is to be constructed to provide additional insurance to the 24 inch line across this four mile area. We have spent to date considerable sums of money in maintenance at Mays and Horse Creeks. Within the past three or four weeks we have had a flood which damaged the protective structure at Mays Creek. There is a direct drop or difference in stream bed elevation immediately below the 24 inch line crossing of approximately fifteen feet. We have a similar condition at Horse Creek. We propose to construct an 18 inch loop line, as explained, in the year 1942, at a cost of $147,995.

The work referred to in Item 16 for the relocation and extension of the 18 inch line at West Nishnabotna River is now in progress. That is also true of the work referred to in Item 17 pertaining to the laying of a 12 inch loop at Grand River.

Item 18 refers to cathodic protection which we propose to install on approximately three miles of the main line in each of the two years 1941 and 1942..

Item 19 provides for the raising of 36 three inch blowoffs in 1940 at a cost of $792.00.

Item 21 covers the installation of 24 inch pipe to replace gates Nos. 49 and 53. This work has been completed.

Page 11 shows the book cost of property retired and salvage with reference to the capital expenditures shown on page 10.

Passing to page 12 of Exhibit 105, Item 1 provides for the replacement of drips. These drips are to be replaced for the reasons already given in connection with other drips. There will be one drip replaced in each of the three years, 1940, 1941 and 1942.

The second item reads "Replace River Headers."
715 One header will be replaced in 1940 at an expense of
$1,696, and one in 1941 at a cost of $1,709. Other headers will be replaced through the years 1942 to 1945, inclusive; one in 1942 at a cost of $2,805, one in 1943 at a cost of $1,709, one in 1944 at a cost of $1,696, and another in 1945 at a cost of $1,696.

Item 3 provides for the installing of six inch blowoffs, beginning in 1939 and ending in 1944, at a cost of $346. Two of these blowoffs will be installed in 1939, three in each of the succeeding four years, respectively, and one in 1944.

Item 4 provides for replacing the 24 inch line at Bridge Creek. Bridge Creek is crossed with a single line. The crossing is about one mile north of Sigourney, Iowa. The reasons for replacing this 24 inch line at Bridge Creek are the same as have been given for the replacing of other similar crossings, such as those at Walnut Creek, Middle

Nodaway River, South River and Box Elder Creek. This work will be done in 1941.

Item 5 refers to the construction of a 12 inch loop line at English Creek. This work will be done for the same reasons that have been given for the construction of a loop line on Box Elder Creek. English Creek is now crossed with a single 24 inch line one-half mile east of main line gate No. 63 on Exhibit 104. The loop line will be installed in 1941.

Item 6 has to do with the installing of 161 coupling sleeves. These coupling sleeves will be installed for the reasons stated in explaining other coupling sleeve installations. The expenditure has been approved and the work will be done as soon as weather conditions permit.

Item 7 provides for the purchase of land in fee in connection with coal mining operations. At the time the rights of way were purchased for the construction of this 24 inch pipeline, it was necessary to include in some of the grants a special provision relative to the pipeline company's obligation to purchase land if and when coal is mined on the respective properties. In 1937 we were required to purchase in fee some land along the pipeline in order to prevent coal mining operations near by and under the pipeline. This is strip mining ordinarily, although there is some shaft mining involved. In the year last mentioned we purchased a strip of land containing 20 acres across the Northeast ¼ of Section 20, Township 75 North, Range 18 West, Marion County, Iowa.

The right of way grants under which these fee purchases must be made to protect against coal operations either specifically state the price that we will be required to pay or state that we will be required to pay the price that a coal operator would pay for the purchase of that particular land. In the 1937 purchase we made at the rate of $300 an acre, or a total of $6,000.

We have reviewed the right of way grants and have
716 found three grants which contain specific provisions
requiring the company to purchase the land as a protection from coal mining operations. In these grants the number of acres is specifically set forth. We are required to buy only as mining operations approach.

There is a strip mine now in the Northeast ¼ of Section 20, Township 75 North, Range 18 West, Marion County, Iowa, and shaft mine operations in the Northwest ¼ of that same section. There are also coal mining operations in the Northwest ¼ of Section 21 and the North ½ of Section 22, same Township and Range. The strip mining operations are already in reasonably close proximity to the pipeline. In Sections 21 and 22 the mining operations are practically adjacent to the pipeline at one point and approximately an eighth of a mile from the pipeline at another point. The shaft mining operations are now in progress in the Northeast ¼ of Section 20. There is a shaft on the south side of the pipeline and an air shaft on the north side of the pipeline. The program of this coal operator calls for the connection of these two shafts, which will place shafting or tunneling directly below the pipeline.

This grant provides that we are to purchase all of the land north of the pipeline in the North ½ of the Northeast ¼ and a strip ten rods wide south of and parallel to the pipeline at the price which a bona fide purchaser would pay for coal mining purposes. We have determined that price to be approximately $300 an acre.

We have a right of way grant in Section 19, same Township and Range, which would require us to purchase the land at $300 an acre, to the total amount of $36,000. In our grant in the Northwest ¼ of the Northwest ¼ of Section 21, same Township and Range, the purchase price of the land is fixed at $4,650. These three amounts total approximately $50,000. We have provided an amount of $5,000 for each of the ten years from 1939 to 1948, inclusive, for the purchase of this coal land. It is our judgment that some time during that ten year period we will be required to spend that sum of money for the protection of the pipeline from coal mining operations. It may be spent in two years, or it may cover a three or five year period.

Questions by the Examiner.

The 1937 purchase covered one tract consisting of 20 acres, at $300 an acre, which with these other three tracts would make four tracts in all.

Direct Examination by Mr. Hedrick.

(August 2, 1939)

We will proceed now to Item 8, which provides for the replacing of three 12 inch lines across the Mississippi River in the years 1944, 1945 and 1946. The Mississippi River

crossing is located south of Muscatine, Iowa, and con-
717 sists of six 12 inch lines. The overflow areas on each side of the river are crossed with two 18 inch parallel lines. This crossing was constructed in 1931, and the time of construction was approximately two and a half months. Those lines were constructed by a separate contractor from those constructing the main line. We had a contractor who was experienced in handling submarine and subsurface construction to construct this particular crossing. These lines across the Mississippi are laid at depths below the river bed varying from zero to four feet. We were required by the War Department to place the line nine feet from the mean low water elevation to the top of the pipe across what the War Department describes as the main channel. We have a warning sign to navigation installed on the west levee of this river, right opposite the pipeline crossing. This sign is large enough to be read from any vessel in the navigable channel. This is to prevent the dragging of anchors in that particular area, which might damage the pipeline.

The reasons for installing three new lines across the Mississippi are identical with those which have been given for installing new lines across the Missouri and Canadian Rivers, namely, to guard against loss by corrosion, fatigue, structural weakness, and direct action by the force of the stream or changing river bed.

As we approach the larger markets the necessity for continuity of service increases. In other words, if we had a break causing an interruption of no more than a day or so on the south end of the line, we might have enough gas packed into the line so that Chicago would not be entirely without gas. If, however, the break occurred near Chicago, the period through which gas would be available to Chicago would be very much shorter. In order to reinforce the Mississippi River crossing, in our judgment it is absolutely necessary to construct three new 12 inch lines across the river, one in each of the three years already stated.

Cross-Examination Interposed by Mr. Slaff.

We have spread out all of the work which we have proposed to do for the reason that there are limited times during the year that such work can be done. We are limited by weather conditions, by time and load conditions.

These are the three main factors that limit us. We can't build a crossing at the Mississippi River when the river is frozen over. It is not practical to do so in the light of the requirements of the War Department. The period during which we can do this character of work with economy starts the latter part of April and ends in September. About September our domestic and heating load comes on. Thus we have four or five months within which to do this character of work.

Then we have considerable work going on over the entire pipeline each year in addition to these particular items. Our organization must inspect and supervise all that work. If we had only one project like the Mississippi River crossing, we could handle it ourselves satisfactorily. This work would be contracted.

Nevertheless we must have proper supervision and inspection of the work that is going on. We inspect all construction work let to contractors.

Item 9, captioned "Cathodic Protection," calls for an expenditure in 1941 and 1942 for protecting approximately 3.2 miles of pipeline in each of those two years.

Item 10 provides for raising 60 three inch blowoffs in 1940. These blowoffs will be raised for the same reasons we have given for the raising of other blowoffs.

On page 12 is shown the book cost of property retired and the salvage as related to the additional capital expenditures shown.

You ask what is the matter with the weather at this time that prevents our installing the coupling sleeves referred to at page 10, Item 11. In order to install coupling sleeves and recoat the pipeline with a paint protective coating, it is absolutely necessary to have the pipe thoroughly dry in order to apply the coating efficiently. The moisture accumulates on the outside surface of the pipe on account of the difference in temperature between the pipe and the atmosphere. This occurs for the same reason that moisture gathers on the outside of that water pitcher there. It is condensation. Condensation is more severe when the humidity of the weather is high. We have attempted to devise means to dry off water from the outside of the pipe in order to apply the protective coating. The efforts have been unsuccessful, and we have to wait on a proper relation between humidity and temperature of the air and pipe before this work can be done. That will occur in the cooler months of the year, beginning about September.

Questions by the Examiner.

You ask why on page 12, in connection with the 24 inch line over Bridge Creek, the ratio is about seven to one between the capital expenditure and the book cost of property retired, whereas in the case of the Mississippi River crossing the ratio is two to one. Bridge Creek shows a capital expenditure in 1941 of $8,833 and a retirement of $1,499. When Bridge Creek was originally constructed in 1931 the contractor submitted unit costs for the construction of an entire section of the pipeline. When he bid on the particular section of the pipeline which he constructed, he did not bid a specific item for this crossing, like he would at a multiple river crossing, for example. The unit costs that applied to the construction of this crossing were the same that applied to any normal crossing.

It is more expensive to construct a pipeline across a stream than on dry land, and that expense we are now discussing is averaged out in his entire unit price. Now, we have to construct this line at one specific location, and it will cost considerably more than if we were constructing a normal pipeline across level country. The added ex-
pense is due to the cost of moving in and out equip-
719 ment and is in effect an overhead cost. The added
cost in there at the present time is also due in part to
increased taxes, shorter working hours and higher wages. All those items affect the cost of doing work as of June 1, 1939, as compared with doing it in 1930 and 1931.

You ask as to the type of equipment ordinarily used in constructing such a crossing. It takes dragline equipment; and in the majority of this work in Iowa, which is detailed on page 18 of Exhibit 105, we have had to use steel sheet piling in the excavation of a trench to get the line deep enough below the future gradient of the stream.

The retirement of $1,499 represents the average cost, that is, what it actually cost us, in money paid to the contractor plus the cost of material that actually went in there, at the time of the original construction. At the time the line was constructed across Bridge Creek the contractor submitted a bid which was accepted for the construction of 100 miles or more of pipeline, which included some of the streams that necessarily would have to be crossed. He submitted unit prices per foot for that work and did not submit special bids for any of the stream work.

In the case of the Mississippi River crossing he submitted a bid only for a river crossing and that contemplated river work only, the unit costs for which are considerably higher than the unit costs for construction of a hundred miles of pipeline. I can illustrate that by referring to the manufacturing of automobiles. If a machine shop be designed to construct a single automobile, the expense would be many times more than the expense of manufacturing automobiles in a plant such as that of Buick or Ford.

Direct Examination by Mr. Hedrick.

Turning to page 13, we find the first item is captioned "Replace Drips." The necessity for this replacement has already been explained. One drip will be replaced in each of the years 1940 to 1944, inclusive.

The second item is entitled "Replace River Headers." The necessity for the replacement of river headers has been explained. In 1940 we will replace one 18 by 12 inch header; in 1941 one 24 by 18 inch header; in 1942 one 24 by 12 inch header; in 1943 one 24 by 18 inch header; in 1944 one 18 by 12 inch header; in 1945 one 24 by 18 inch header; and in 1946 one 24 by 18 inch header.

The third item provides for the installation of 14 six inch blowoffs. The necessity for those has been explained. Two will be installed in 1939, two in 1940, two in 1941, three in 1942, two in 1943, two in 1944, and one in 1945.

Item 4 involves an expenditure at Brush Creek. That creek is now crossed with a single 24 inch pipeline at a point two-thirds of a mile east of main line gate No. 76, north of Depue, Illinois, as shown on Exhibit 104. The installing of a 12 inch loop line at this crossing is
720 necessary for the reasons already stated with reference to the installing of similar loops which I have already discussed. The only difference is that this crossing is near the Chicago market, which, as I have explained, makes it even more necessary as insurance of continuity

of service. The overflow area is 350 feet, and the loop line will be 1000 feet long. The difference is due to the fact that in order to secure an adequate location for the gate valves and for proper blocking, it is necessary to install those valves on the hills on each side of this overflow area. We try to place the headers outside of the overflow area and on ground where the conditions are entirely stable.

Item 5 provides for the installation of 31 coupling sleeves in 1939. This work is approved and will proceed as soon as weather conditions permit.

Item 6 provides for installing 42 coupling sleeves in 1940. I have explained the necessity for installing coupling sleeves in connection with my testimony concerning the installation of similar coupling sleeves in Districts 5-W and 5-E.

Item 7 provides for the replacing of 24 inch line at Devils Slough. This slough is crossed with a single 24 inch line and is located less than a mile west of the I. & M. canal in Illinois. We are particularly concerned with erosion in this area. At the present time we have a program for replacing 165 feet of 24 inch pipe, the work to be done on Labor Day. We have chosen this day because load conditions are low. Another reason is that we have a delivery to the New Jersey Zinc Company at Depue, Illinois. They are unable to take and accept a reduction of gas flow until that date. In fact, they have required this advance notification. This is due to the time involved in the shutout in connection with this work. We notified the customers that we proposed to do this work, and the New Jersey Zinc Company advised us that they could not accept reduced deliveries until Labor Day.

The pipe to which I referred is located between Devils Slough and the I. & M. canal. Soil conditions in that area are of a peat bog nature. There is considerable moisture in that section of the country, which aggravates the corrosion conditions. This is similar soil to that where the pipeline break occurred last year near Sheffield, Illinois, to which Mr. Floyd C. Brown testified. For these reasons we are going to replace the 24 inch line across this slough and at the same time lay this line at a depth of six to eight feet below the present elevation of the stream. About 300 feet of pipe will be involved in this replacement.

Item 8 refers to the replacement of three 12 inch lines across Fox River. That river is now crossed with six twelve inch lines located just northeast of Ottowa, Illinois, as appears on Exhibit 104. The overflow area on the west side of Fox River is crossed with two 18 inch pipelines. Fox River is a navigable stream, and the crossing of this stream was done in accordance with the specifications and requirements of the U. S. War Department.

721 Those War Department requirements provided that the top of the pipe should be two feet below the elevation of the stream bed. The stream bed in Fox River is solid rock. In order to construct this crossing the contractor was required to excavate a trench in solid rock for each of these six 12 inch lines by dynamiting under water. Due to the roughness of each trench in which the 12 inch lines are laid, this rock causes penetration of the protective coating on the pipe, which is breaking down. The result is corrosion.

I might add that the covering above the pipe in the trench is also rock, which is the only material available at that place. We are going to replace three of the 12 inch lines across this river, one each in the years 1943, 1944 and 1945. In fact, we are going to install three new lines across the river as a safety measure. We are unable to determine specifically everything that is taking place in each of those river lines. In such a situation we cannot take a chance of interruption of service at any time for any reason. This work is to be done as a result of our best judgment in the proper and efficient operation of this pipeline system. That is also one of the reasons for the replacement of the lines across the Mississippi and Missouri Rivers.

Cross-Examination Interposed by Mr. Slaff.

Yes, these lines will be replaced at the same location which they now occupy. It will be more economical in this particular instance to remove the present lines from these rock excavated trenches than it would be to have to excavate additional trenches. We will not have to blast new trenches across the river. Naturally, there would be some danger in blasting close to the pipeline.

Direct Examination by Mr. Hedrick.

Item 9 presents another instance of cathodic protection, the need of which has been explained heretofore. In each of the years 1941 and 1942 cathodic protection is to be installed for approximately four miles of 24 inch line.

Item 10 provides for the raising of three inch blowoffs, to be done in 1940. The necessity for this work has been explained. 46 blowoffs are involved in this item.

Item 11 provides for the replacement of 24 inch line across Brush Creek. This is the same creek as referred to in Item 4 on page 13. The reasons and the necessit for the replacement of 24 inch line across this creek are identical with those given in support of the replacement of similar line crossings, with the exception that again we are approaching closer to the main delivery points of the system. This work is to be done in 1941 at a cost of $8,833 for a section of 300 feet of 24 inch line. This line is in addition to the loop line that will be installed under Item 4. When we get through with this replacement we will have two lines across Brush Creek.

722 *Questions by the Examiner.*

You ask if we would not be in the same fix if we had an interruption any where along the line between Chicago and Texas as if it were near Chicago. That is true, except that if we assume an interruption in the vicinity of Beaver Creek, Oklahoma, we would have available all the line pack which is in the line from Beaver Creek to Chicago. If we have an interruption at Fox River, which is within 30 or 40 miles of Chicago, obviously our line pack would be very, very small from which we could draw in supplying the market. Also we have other loads along the pipeline for which we are committed for delivery.

Direct Examination by Mr. Hedrick.

We can no more cut off the firm load for Davenport, Iowa, for instance, than we can for Chicago. We can cut off all the industrial loads. The load along the pipeline, not counting Chicago, including industrial sales, amounts to approximately 30 million per day, as against a delivery of 185 to 190 million cubic feet to Chicago. What I am trying to say is that in case of an interruption that has a short duration, we can stand an interruption on the south part of the line better than we can on the north. If we had a major interruption lasting a period of several days, regardless of whether it was near Chicago or in Oklahoma, the results as far as Chicago and the eastern points of delivery are concerned would be the same.

It is these major interruptions we have in mind in taking these precautions. A major interruption might be repaired in 24 hours or it might require three or four days for repair, depending entirely upon its nature and location, the condition of the soil, and the weather conditions prevailing at the time.

I can give you an illustration of what I am trying to say. In the testimony of Mr. Floyd C. Brown he referred to what we know as the Sheffield break. This break occurred at a point approximately three miles northwest of Sheffield, Illinois, about 7 A. M. on Sunday, February 13, 1938. The failure resulted because the ground was frozen and then thawed out by a warm period which took the frost out of the ground. During this period of warming up we had continuous rains, which created a very unstable soil condition at the point of failure. The exact location of the failure was on an old lake bed and the soil was of a peat bog nature. The result was that the moisture got under the pipe, resulting in buoying or floating it out of the ground, causing an angular deflection at the coupling at that location. The pressure of the gas within the pipe was then sufficient to cause a vertical component of force and a complete failure of the line.

The failure was observed immediately at the discharge gauge at Station 10, just west of the break. A report of the failure was immediately made to the dispatching office in Chicago. The dispatcher got in touch with Mr. Kesinger, Mr. Davidson, Mr. Bulla and myself—in fact, all men in the organization who are responsible for continuity of service. At that time each customer was 723 notified that a disruption existed in the pipeline; and immediate steps were taken to remove the interruptible loads and also to protect all domestic firm sales. Customers like the Peoples Gas Light & Coke Company immediately put their standby equipment in operation.

The next step in a situation of that kind is to notify the field organization responsible for that part of the pipeline. They in turn notify all subordinate organizations down to the maintenance men. All the emergency repair equipment is immediately placed on trucks and cars and started for the location of the break. We also arranged for the use of tractors, horses and wagons, trucks, pumps, and all other equipment which we thought might be needed in making the repair. That included welding machines.

This particular repair was located approximately three miles from a concrete highway. As a result of the continuous rains the roads were very muddy and rutty. We were required to move all this equipment from this concrete highway to the location of the break over these muddy roads. After we delivered our material to the road, that is, the dirt road immediately west of the location of the break, we were required to move that equipment in to the location of the break across a peat bog soil condition. Meantime the break had to be isolated immediately by closing the main line gates on either end of the break.

In moving the equipment over these muddy roads, I personally went in over my knees in this peat bog soil, so it is apparent what would happen in the necessary hauling of heavy equipment across that same area.

We started to build a wood or corduroy road through this bog by hauling in railroad ties obtained from the Rock Island Railroad in Sheffield and the towns and areas adjacent to Sheffield. In fact, we did haul in from 800 to 1000 ties.

Exhibit 85, introduced in connection with the testimony of Mr. Floyd C. Brown, contains a number of pictures of the Sheffield break. The location of the break is shown in the top picture, or picture No. 1, just west of the trees which are in about the center of the picture. Picture No. 4 will give you a better idea of the water condition existing at the exact location of the break. The rupture of the pipe was practically in the exact center of this water. The parted pipe will be observed in Picture No. 5, which shows the pipe after it was pulled out of the 24 inch coupling.

Referring back to picture No. 1, the water in the ruts reflects the elevation of the water table. Picture No. 2 shows the nose of a large tractor partially submerged in the unstable soil. You will note the entire radiator is practically covered. Picture No. 3 shows the construction of this corduroy road, using railroad ties. A tractor is used in placing those ties.

Within two or three hours men and equipment started to arrive at the point on the road near the location of 724 this break, and we at once took means to transport the equipment across this unstable soil condition to the location of the break, which is shown in picture No. 4 and also in pictures Nos. 5 and 6. We were able to get a few small pumps to the location of the break by Sunday afternoon and place these pumps in operation. They were not sufficient to handle the large volume of water, however. We at that time made arrangements for securing or bringing additional larger pumps to this location. We immediately took steps to secure two cars of cement. This we could not obtain closer than LaSalle, Illinois, which is east of Sheffield. We made arrangements with a local lumber and supply dealer at Sheffield to have this cement hauled from the plant at LaSalle to the location of the break. This had to be done on Sunday. In fact, there was a time when the cement company refused to permit cement to be hauled from their plant by trucks. They advised that it would have to be handled by railroad. We were able to persuade them of the emergency existing and they did permit the hauling of this cement by trucks on Sunday night. The cement was needed for constructing cofferdams or dams to confine the water so that we could pump it out.

We were aided considerably by the freezing temperature of the night following the break. This permitted a more ready movement of the equipment into the location. On Monday morning we had sufficient material on hand to proceed with the dewatering of this excavation which was blown out by the gas escaping from both ends of the pipe, forming the lake shown in picture No. 4.

The break was finally repaired on Monday evening about 11 P. M. We took immediate steps then to weight the pipeline across these peat bog areas. The emergency protection was gravel filled sacks. We installed final or permanent protection by the use of concrete anchors and by installing steel welding sleeves on each coupling.

That break influenced the policy of the company in purchasing additional tractors, pumps and trucks for such occurrences as might happen in the future. Before leaving this, I would like to mention that we employed over 300 men to assist with the repair of this particular break.

Cross-Examination Interposed by Mr. Slaff.

Yes, our firm supply to Chicago was interrupted. We had partial interruption from Sunday morning about seven A. M. until the completion of the repair, which was about 11 P. M. Monday, February 14. I am referring to the domestic load. Mr. Floyd C. Brown stated in his testimony that the cost of this interruption by loss of gas and including the cost of repair was some $248,875. The cost of the physical repair was slightly in excess of $42,000.

Direct Examination by Mr. Hedrick.

Item 12 provides for installing six 12 inch automatic valves at Fox River. As pipeline operators, we have 725 realized for a number of years the necessity for providing some means or device for shutting off gas when a pipeline break occurs, thereby retaining the maximum amount of gas in the pipeline after the break and preventing the flow of that gas to the atmosphere. In 1934 we made our initial tests and did our initial experimental work and made our initial contacts with the various valve manufacturing companies for the design and manufacture of automatic valve equipment. By automatic I mean that the valve will close completely without the aid of manual operation. Although they encountered several difficulties in the design, such a valve was finally successfully designed and manufactured, beginning about March or April, 1939. We made a number of tests, simulating as near as possible actual main line breaks and resulting loss of gas. As a result of these tests, we were satisfied that the valve with the automatic feature would perform the duty desired. We have formulated a program for the installation of automatic valve equipment. The first equipment of this nature is scheduled to be added this year by the installation of six of these valves at the east side of the Fox River crossing. The management has given approval to this installation and the valves have been ordered.

Item 13 provides for the installation of two 18 inch automatic valves at the I. & M. canal. This canal is in the central part of Illinois, as appears on Exhibit 104. The expenditure is to be made in 1940.

Item 14 is for the installation of two 18 inch automatic valves at Mud Creek, just west of the I. & M. Canal. This work will also be done in 1940.

Item 15 provides for the installing of two 18 inch valves at Mill Creek, 21 miles west of Mud Creek, in the year 1940.

Item 16 provides for the installation of two 18 inch automatic valves at the east 18 by 24 inch header of the Mississippi River crossing, in the year 1940.

Item 17 is for the replacement of main line gate No. 76, as shown on Exhibit 104, with 24 inch automatic valve equipment. It is in the vicinity of Depue and Princeton, Illinois.

This work is scheduled to be begun in District 6 only at this time. This is in accordance with our policy of protecting the east end of the pipeline system, due to the lack of line pack as we approach Chicago. As already stated, it is the policy of the company to protect the line at the north end more than at the south end.

Question by the Examiner.

You ask what is the actuating principle of these automatic valves. This valve is actuated by a piston. It is what we term the plug type valve, manufactured by the Merco Nordstrom Company. We have directly installed on this valve a cylinder and piston. The valve is operated by means of this piston, through a rack and segment gear.

The gear is directly connected to the stem of the valve.
726 There is an auxiliary tank installed close to the valve installation which is connected to the main pipeline. The pressure which exists in the pipeline also exists in the tank. The tank contains gas.

There is a 1/32 inch orifice between the tank and the 24 inch line. This orifice permits fluctuation of pressure in the tank as the pressure fluctuates in the main line, which may be 10 to 15 pounds in a 24 hour period.

There is another connection made from this tank to the piston actuated valve. In case of break, the pressure on the pipeline decreases suddenly and the pressure on one side of the piston likewise decreases. The force of the pressure in the reservoir will be exerted against the opposite side of the piston. The gas cannot flow back into the pipeline due to this orifice restriction. The major flow is into this piston actuated valve. The principle in general is identical with the air brake installation on a railroad train. Contrary to general belief, when the engineer makes a service application in his locomotive he does not increase the air pressure on the train system. He releases or decreases the air pressure. That sets in motion what is known as a triple valve, which in turn admits pressure contained in an auxiliary reservoir installed under each car. The force of that pressure actuates the piston under that car, which controls the entire braking mechanism.

Direct Examination by Mr. Hedrick.

The book cost of property retired and the salvage as related to the additional capital expenditures are shown at the bottom of page 13.

Cross-Examination Interposed by Mr. Slaff.

The construction of the pipeline in District 6 was handled by one contractor, unless the Mississippi River crossing be regarded as in District 6. That crossing was handled by another contractor. The explanation for the difference in book cost of drips shown on line 1 and in book cost of property retired is that those two drips which will be retired in 1943 and 1944 respectively were installed by the company and not by the contractor.

Direct Examination by Mr. Hedrick.

Turning now to page 14, the first item is "Replace 8 inch River Lines, Davenport, Mississippi River." This river crossing is a part of the branch line which connects the 24 inch main line with our meter setting at Linwood, Iowa, for the delivery of gas to Davenport, Iowa. Two 8 inch lines are now installed across this river.

The channel of the Mississippi at this point is divided by an island. The flow of the river is generally east to west at this point. The main channel is at the north side of the island. An 8 inch line is to be constructed across this river in 1945 for practically the same reasons that have been given for constructing three new lines across 727 the main line Mississippi River crossing. The two original 8 inch lines were constructed in accordance with the U. S. War Department's specifications. The new 8 inch line in the main channel will be laid in rock. We propose to reclaim the old line when the new line is laid. We will still have two 8 inch lines across the river.

Item 2, "Raise Three Inch Blowoffs," relates to work to be done in 1940 for installations of four 3 inch blowoffs. The necessity for this work has been explained. The book cost of property retired and salvage as related to those two items are shown at the bottom of the page.

We pass now to page 15, which is entitled "Pipeline Department, Joliet Meter and Regulator Stations, Additional Capital Expenditures".

Item 1 refers to the replacement of vacuum pumps. A vacuum pump is a small piece of equipment directly connected to an electric motor. The pump is used for removing gas or air from the specific gravity balances. The specific gravity balances are used for determining the specific gravity of the natural gas.

With the exception of Item 7, "Replace Water Softener System," considering Items 1 to 13, inclusive, that equipment and apparatus was all purchased in 1931 at the time the pipeline system was placed in operation. The equipment is used either for determining the measurement of the gas or correcting for the measurement of the gas. It is our judgment that this equipment will become worn out and deteriorated to the point where it is no longer serviceable and will be replaced in the respective years as set forth in the exhibit. Item 7, the water softener, was purchased about three years ago and will be replaced in 1946.

Item 14 provides for the construction of a porch at the Joliet regulator station. This work has been approved and is now in progress.

The book cost of property retired and the salvage in connection with the expenditures on this page are shown at the bottom of the page.

Page 16 deals with additional tools for the use of the pipeline department. Use will result in the deterioration of this equipment and will wear it out to the point that it is no longer serviceable or safe to use. This, of course, will necessitate their replacement. That applies to the melting kettles in 1942.

The district numbers shown on this page are the same as those shown on Exhibits 103 and 104. The melting kettles will be replaced in 1947 and 1948 for the reasons given. In 1940 the Sterling pumps are to be replaced on account of the worn out equipment. In 1945 a diaphragm pump is to be replaced. In 1946 the Sterling pumps purchased in 1938 will be replaced. In 1948 the Sterling pumps purchased in 1940 will be replaced.

In District 3 an electric welding machine has been
728 purchased in 1939. In 1942 another will be purchased to replace one purchased in 1936. In 1943 another will be purchased to replace one installed in 1937. In 1944 another welding machine will be added to the present equipment. In 1945 another will be purchased to replace the one purchased this year. In 1947 an additional welding machine will be purchased. In 1948 another will be purchased to replace the one to be purchased in 1942. In 1949 another will be purchased to replace that to be purchased in 1943. In 1950 and 1951, respectively, machines will be purchased to replace those to be purchased in 1944 and 1945.

In District 4 a welding machine will be purchased in 1943 to replace one purchased in 1937. A welding machine will be added to the equipment in 1947. In 1949 one will be purchased to replace the one purchased in 1943.

In District 5 a welding machine will be added in 1942, and in this district two machines will be purchased in 1943 to replace those purchased in 1937. In 1947 two welding machines will be added to equipment, and in 1948 and 1949, respectively, welding machines will be purchased to replace those to be purchased in 1942 and 1943.

In District 6 a welding machine will be purchased in 1942 to replace that purchased in 1936. This is a smaller machine, which accounts for the difference in cost. In 1943 another welding machine will be purchased to replace that purchased in 1937; and in each of the years 1944 and 1947 a welding machine will be added to equipment. In 1948, 1949 and 1950 welding machines will be purchased to replace those to be purchased in 1942, 1943 and 1944.

The adding of new welding machines to the present equipment will be necessary on account of additional maintenance which the pipeline will require in future years, as I have heretofore testified.

Items 4 and 5 provide for the replacement of Rex gas engine driven centrifugal pumps. The present pumps were purchased in 1938 and will be replaced in 1946.

Item 6 deals with rotary scrapers which will be purchased in 1946 to replace those purchased in 1938.

Item 7 provides for electric lighting units to be purchased in 1948 to replace those purchased in 1938.

Item 8 provides for air compressors to be purchased for District 3, one to be added in 1944, one to be added in 1945, one to be purchased in 1946 to replace the one purchased in 1938, and one to be purchased in 1952 to replace the one purchased in 1944. The reason for the difference in cost of the last item is that the compressor to be replaced in 1946 was equipped with a number of auxiliary tools.

In District 4 the air compressor purchased in 1935 will be replaced in 1943; and in 1951 we will replace the compressor, less the tools, to be purchased in 1943.

729 In District 5 we will add two air compressors in 1943. In 1946 and 1951 air compressors will be purchased to replace those purchased in 1938 and to be purchased in 1943.

In District 6 an air compressor will be added in 1943, one will be purchased in 1944 to replace one purchased in 1936, and compressors will be purchased in 1951 and 1952, respectively, to replace one purchased in 1943 and one purchased in 1944, less the tools.

Item 9 deals with a one-half yard power shovel with drag line and pull shovel equipment. This is new equipment, the necessity for which was explained in the testimony under Texoma Natural Gas Company system, referring to heavy excavating equipment for repairs which will have to be made to the pipeline in subsequent years. I refer to Item 9 on page 6 of Exhibit 105. Full shovel equipment will be purchased in 1947 for each of Districts 4, 5 and 6 in addition to the purchase of such equipment in 1943 for District No. 5.

Item 10 provides for snow plow equipment for trucks and caterpillars to be purchased for the clearing and removing of snow from highways and roads to permit emergency repairs and also to provide the opening of the roads for maintenance work necessary to be carried on. I might state that in the early winter of 1936 we utilized snow shoes and skis in Iowa for covering the pipeline and performing such work as could be done under snow and snowbound conditions in the field.

Item 11 deals with Gould diaphragm pumps. The pumps to be purchased in 1944 are to replace those purchased in 1934. Those to be purchased in 1948 will replace pumps purchased in 1938.

Item 12 deals with a bench drill, which has been approved by the management for purchase. Likewise, Item 13, a pipe cutting machine, has been approved for purchase by the management.

Item 14 shows small miscellaneous tools to be purchased. These are small tools costing in excess of $25.00, to which reference has not been made in the above mentioned items. Our judgment is that these tools will have to be replaced and additional tools will have to be purchased in order properly to maintain and equip our respective gangs in the carrying on of their duties in connection with the operation and maintenance of this pipeline system.

The book cost of property retired and salvage relating to expenditures shown on page 13 are shown on page 17.

Questions by the Examiner.

You ask how this compares with the tool account on page 7. The latter is a summary. You will note that on page 7 for the year 1939 we show expenditures for tools of $3,581. If you will refer to page 16, you will find the total of tools purchased in 1939 in the same sum. In other words, Item 14 on page 16 is for miscellaneous small tools, and Item 8 on page 7 is the total for all tools, including small tools.

730 You ask why I have a diaphragm pump under centrifugal pump instead of down with the others. That pump came under the classification of small pumps. It was just placed in that classification for no specific reason that I can give. This diaphragm pump is a small pump. The Gould diaphragm pumps are hand operated pumps, as shown in Item 11. The C. H. & E. diaphragm pump is a gas engine driven or power driven pump.

Direct Examination by Mr. Hedrick.

It is my considered judgment, based on my experience and upon my knowledge of the pipeline, machinery, equipment and other property of defendants, of the demands upon the same in the course of defendants' operations, and of the physical condition of this property and equipment, that at the prevailing costs of labor and material as of June 1, 1939, the amounts set forth in Exhibit 105 will be expended by defendants for additional capital equipment on or before the respective dates set forth in the exhibit.

(EXHIBIT 105 was offered and received in evidence over the objection of counsel for each of the two Commissions, to whom an exception was allowed.)

Passing now to Exhibit 93, Item 2 on page 2 provides for an expenditure in 1939 of $4,101 to construct one four room cottage for the pipeline department. That is a house for the proration clerk located at Fritch, Texas. As the number of wells increases we need additional clerical assistance in handling the proration of the wells over the entire gathering system.

Item 4 provides for a similar house in 1940 at the same cost, $4,101, this house to be for a gas engineer employed to determine rock pressure, open flow and back pressure in connection with the operation of the wells over the entire gathering system.

Item 6 provides for the construction of a four room cottage in 1941 at a cost of $3,815. That house is for a pipeline maintenance foreman to be added to the organization in that year. These foremen have immediate charge of the maintenance gangs and handle all maintenance work throughout the gathering system in connection with lateral lines and booster stations.

Item 7 provides for the construction of four 4-room cottages in 1942 at an expenditure of $15,260. One of these houses will be for a welder who will be required on account of the increased welding work for the pipeline and for the compressor stations. One will be to house an automobile mechanic, who will be required for the added automotive equipment. The third house is for an assistant meter superintendent. The work of this division of the department will increase as the number of wells increase along the gathering system. The fourth is for a gas engineer.

Item 8 provides for the construction of two 4-room cottages at an expenditure in 1944 of $7,630. One of these
731 is for an assistant pipeline superintendent who will
be needed in connection with the added work and responsibilities due to the added investment to be made in the gathering system in connection with additional wells, lateral line construction and booster station operation. The other will be occupied by a chart changer, who will be added to the organization in 1944. Chart changers are

used for replacing the orifice meter gauge charts and to assist in the servicing of booster stations.

Item 9 provides for the construction of two 4-room cottages for the pipeline department in 1947 at a cost of $7,630. These houses are for a maintenance foreman and a truck driver, who will be added to the organization in that year to meet the requirements of the system.

Item 10 provides for the construction of one four-room cottage in 1949 at a cost of $3,815. This house will be occupied by an additional chart changer who will be required at that time.

Item 1 on page 6 of Exhibit 97 provides for the construction of eight 4-room cottages in 1939, at a cost of $33,576. We are endeavoring to locate the pipeline organization closer to the actual operations because they are needed there for emergencies. The houses also provide for the welfare of the personnel. We are particularly interested in the welfare of each employee from the standpoint of continuity of service and their value to the organization.

In 1940 the pipeline department will require a house at Station 3 for a pipeline welder. In the same year a house will be constructed for an additional pipeline welder at Station 4. During the same year at Station 2 the bunk house will be converted into a dwelling for a line welder; and at Station 5 a house will be constructed for a pipeline welder. In 1941 a house will be constructed for an additional pipeline foreman at Station 5, and during the same year a house will be constructed for a pipeline superintendent and one for a pipeline welder at Station 6. During the same year a house will be constructed at Station 8 for a truck driver, and one at Station 9 for a meter inspector. A meter inspector is responsible for the operation and maintenance of the meter equipment.

(Counsel handed the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Operation and Maintenance, Pipeline Department, Witness R. G. Strong," which, at the direction of the Examiner, was marked Exhibit 110 for identification.)

The subject matter dealt with on page 1 of Exhibit 110 is set out more in detail on page 2. Line 2, entitled "Natural Gas Pipeline Company of America," is set out in more detail on page 7 of the exhibit. The detail of

Lines 1, 2 and 3, page 2 of the exhibit, entitled "Gathering System, District No. 1;" "District No. 2," and "Booster Stations," is set out more fully on pages 3, 4 and 5 of the exhibit.

Passing to page 3, the items on Lines 1, 2, 3, 4 and 5,
for the years 1939 to 1954, inclusive, were calculated by
determining a unit cost per mile of pipeline installed
as an average in the years 1936, 1937 and 1938. In
732 other words, the unit costs were prepared from the
actual cost of operating the gathering system in those
three years.

I mean the unit cost per mile of pipeline installed was calculated in that manner. That factor unit cost per mile per year was applied to the miles of pipe which are to be added in each year from 1939 to 1954. The same explanation is given for material, for car and truck, and for damages, with the exception that when we are required to pay damages or to pay for repairs to equipment such as pipe repairs, coupling repairs, repairs that have not heretofore been done, those damages and repairs will be added to the unit cost as projected in each of the years. The traveling expense shown in Line 5 is projected on a unit cost per mile basis.

Under Line 6, "Meters and Regulators," a unit cost was developed from the actual expense from 1936 through 1938 based on the number of meters serviced during each of those three years. That unit cost was applied in projecting the cost from 1939 to 1954, inclusive, based on the number of meters to be added to the gathering system in each of those years. That in turn is, of course, based on the number of wells to be drilled, as shown by the testimony of Mr. Bussard and set out in his Exhibit 100.

The cost of material and labor was arrived at by a unit cost, not by using the prices of June 1, 1939, representing an average actual cost during the years 1936, 1937 and 1938. We have certain items such as repairs to pipe, repairs to drips, the cost of replacing a drip, that is, the reclaim cost of replacing a drip, the reclaim of lateral lines, the cost of the reclaim, repairing river lines, all of which is work that is not represented by the actual unit cost arrived at for these years 1936, 1937 and 1938.

In determining the cost of labor that goes into operation and maintenance, we developed a unit cost from actual expense incurred from actual operation over the three year period, 1936, 1937 and 1938. We applied that unit cost to the number of miles of pipeline we expect to have in place during the years 1939, 1940, and so on. That would apply to the material as far as the unit cost developed is concerned.

The labor costs on June 1, 1939, were practically the same as for the years 1936 to 1938, inclusive. I think I can say they were the same, as I do not remember any changes that may have taken place during that period of time. The only difference would be the decrease in the number of working hours, which might affect the cost of operation, and that would tend to increase the labor costs above the average that I have used in projecting this expense. In other words, if I had used the June 1, 1939, labor cost, taking into consideration the decreased labor hours, it would show a greater amount.

Items 8, 9 and 10, under "Maintenance," were arrived at in the same manner as explained under "Operation," by determining the unit cost per mile of maintaining
733 the lines during the years 1936, 1937 and 1938. To those costs as shown for the years 1939 to 1954, inclusive, I have added the expense of material, labor, transportation, and car and truck applying to the additional miles of pipe that would be added to the gathering system.

Cross-Examination Interposed by Mr. Slaff.

For each of the years after 1939 we have two factors, one the unit cost per mile that we have developed over the three year period 1936 to 1938, inclusive, applied to the number of miles of pipe we expect to have in place. Then there is an additional item of expense for each year for certain operation and maintenance for which we cannot or have not developed unit costs. There is no detail of that breakdown. The detail is shown in my working papers.

Direct Examination by Mr. Hedrick.

These working papers will be available to counsel and their engineers at their and my convenience.

Line 11, "Meters and Regulators," was calculated from the unit cost of actual maintenance of the meters and regulators installed during the years 1936, 1937 and 1938, applied to the meters and regulators to be added to the gathering system in the years 1939 to 1954, inclusive, which is based on the number of wells that are to be added to the gathering system during those years, as shown in Exhibit 100.

Cross-Examination Interposed by Mr. Slaff.

The total mileage of pipe in the gathering system as of January 1st of each of the years to which I will refer is as follows: 1939, 230; 1940, 248; 1941, 272; 1942, 288; 1943, 309; 1944, 321; 1945, 336; 1946, 357; 1947, 382; 1948, 398; 1949, 411, 1950, 419; 1951, 426; 1952, 426; 1953, 426; and 1954, 426.

The miles of pipe in the gathering system as of January 1, 1936, were 191; 1937, 206; and 1938, 220. The number of meters and regulators as of January 1, 1936, was 110; 1937, 128; and 1938, 149.

No, I did not use the figures of pipeline in existence as of January 1, 1939, January 1, 1938, and January 1, 1937. I used the figures as of January 1 of the years 1936, 1937 and 1938. Those are the methods that two different people might use. In arriving at this cost I used the pipe that was in place the first of those three years. The pipe that was installed during 1936 was picked up and used as an average during the year 1937. The pipe that was installed in 1938, added to the pipe that was in place on January 1 of that year, will give you the pipe in place as of January 1, 1939, which, with these factors applied, will give you the amount shown under the column "1939."

734 I took the total amount of pipe in place as of January 1, 1936, the total in place on January 1, the following year, that is, the sum of the pipe that was installed during the year 1936 added to the amount that was in place January 1, 1936. That gives you the quantity of pipe which I used for the year 1937.

You ask if in order to get the amount of pipe for that full year 1938 I had to take into consideration the figure I gave you of pipe in place as of January 1, 1939. The answer is no. I gave you the figure of pipe that was in place January 1, 1938. The pipe added during 1938 was not picked up until the year 1939, and then was applied to the January 1, 1939, figures. To be absolutely correct I think you have this in mind: it would be necessary to calculate a weighted average by months or to the extent of weeks, if we want to carry it that far. I realize there is a chance for confusion in here, f

Direct Examination by Mr. Hedrick.

Proceeding to page 4 of Exhibit 110, Line 1, entitled "Horse Power," during the years 1938 to 1954, inclusive, refers to gas engine compressors which are to be installed in what we have termed the booster stations. These have a nominal rating of 40 horse power for each compressor gas engine driven unit.

Under the sub-head "Operation" on page 4 of this exhibit, the cost of operating labor was determined from the actual operating expense which we have had in connection with servicing meters and regulators throughout the gathering system. We have determined that a booster station will require twice the amount of servicing that a meter will require; therefore, we have doubled the operating labor expense shown for the years 1936, 1937 and 1938 and applied that as a factor for determining the cost of booster station operation labor, as shown in Line 2, page 4, in the years 1939 to 1954, inclusive. The year 1938 reflects the actual operating labor expense. That expense is by no means comparable to what in our judgment will be the future expense of operating booster stations. It is much higher on account of the experimental type of operation of the booster station which is now in place. We have been required to pay considerable attention to that unit to determine its operating characteristics. I do not expect the 1938 cost to continue throughout the years 1939 to 1954, inclusive.

Line 3 shows the cost of material for operating the units. This consists largely of lubricating oil and expense for small tools, gasoline, kerosene, waste, rags, etc. We have determined this expense to be $4.50 per horse power per year, wich applied to the horse power installed for each of the years shown, with the exception of 1938, will give the total material operating cost. The 1938 cost of material is lower than the 1939 cost of material for the reason that the station was placed in operation in May, 1938, and was not operated for the full year.

735 Referring to the sub-heading "Maintenance" in Line 6, we determined the cost for maintenance labor by the expense of maintaining personnel, that is, foremen, mechanics and helpers to be used in the maintenance of this equipment. This also includes the transportation of these men about the gathering system. From that study we determined that the cost per horse power per year would

be $4.60, and that factor was used in determining the expense of maintenance labor for the years 1939 to 1954, inclusive.

The maintenance material cost shown in Line 7 was determined by listing the repair parts which in our judgment will be required for the proper maintenance of these units during their existence in the gathering system. The maintenance material cost per horse power per year was determined to be $1.65, and, with the exception of 1938, which reflects actual expense, maintenance material costs were arrived at by multiplying this factor times the horse power installed for each of the years 1939 to 1954, inclusive. In 1954, 80 units will not be operated. Therefore, the total horse power operated will be decreased to the extent of 80 units.

As the additional booster station units are installed, as shown by Mr. Bussard's Exhibit 100 and as shown in the first line on page 4 of Exhibit 110, the costs for the operation and maintenance of those stations and units will increase in accordance with the increase in number of stations and units. I wish to explain that in 1952 the maintenance cost for labor and material has an added amount to cover the cost of reclaiming 25 forty horse power units. That amounts to $4,125 for labor and material, so in checking the expense for 1952 that cost of reclaim will have to be considered.

Cross-Examination Interposed by Mr. Slaff.

The fuel cost for operating the booster stations was determined by actual metered measurements of the gas used in the presently existing booster station. These quantities were applied to the adidtional units as they were installed in the respective years, or are to be installed in the respective years, 1939 to 1954. The cost of that fuel was calculated on the basis of 4¢ per MCF.

Direct Examination by Mr. Hedrick.

Referring to Lines 1 to 6 on page 5 of this exhibit, for the years 1939 to 1954, inclusive, those amounts were determined from our actual past experience as to expenditures and the work represented thereby. In addition, we have determined what in our judgment will have to be done to properly operate this pipeline system and to maintain the efficient organization and personnel that will be required to operate it under the load factors that will obtain. In this connection, as the property becomes older, more operating expense will be required. This includes additional expense for patrolling and walking the line and for the determination and finding of defects in the underground structure. The operating material and car and truck will have additional expense caused by the added program for patrolling and walking the pipeline.

736 The difference between the 1936-1938 average of $3,461 for operating labor and the 1939-1954 average of $4,350 is $889 per year, or approximately $75 a month. That represents one man employed about 50% of the year for additional patrolling.

Cross-Examination Interposed by Mr. Slaff.

You ask what is the explanation for the large figure shown in Line 2 for operating material for 1938. There is an item of expense in operating material for 1938 that in our judgment will not reoccur. The expense shown for 1939 represents more nearly, in our judgment, what the actual expense will be in that year and in subsequent years. If I had used the 1939 figure in 1938, instead of being $968 it would be around $450 or $460.

Direct Examination by Mr. Hedrick.

The car and truck expense is for additional transportation used in patrolling the pipeline as the necessity for patrolling increases during the succeeding years.

"Damages" represent the item of payment to landowners or farmers for the damage to land and property, fences, private roads and so forth, crops, cattle and other stock.

Except for the gathering system, we have used prices of labor and material as they existed on June 1, 1939.

The item of "Traveling Expenses" is the expense of personnel from the Chicago office making inspection trips to the field to determine what work should be done, how it should be done, and when it should be done. That expense does not include the field personnel expense.

The next item is "Meters and Regulators." Those amounts are for the operation of the meters and regulators, and, in our judgment, will have to be expended for the years 1939 to 1954, inclusive, as shown in this exhibit.

"Maintenance Labor" covers the labor expense of making all repairs to the pipeline structure, such as repairs to back fill, erosion protection, repairs to roads, repairs to pipe, repairs to couplings, repairs to valves and fittings, and also the cost of retiring structures from the pipeline as explained under capital expenditures. The whole program of maintenance is one of prevention, that is, the determination of what work has to be done from time to time is based upon a program of prevention rather than cure.

The average for maintenance labor for 1936-1938 was $5,757, and the average for 1939-1954 is $15,637, or a difference of approximately $9,880 a year, or $824 a month, for the line represented by District 2. That represents a personnel of one foreman and six men, the additional average that will be employed for maintenance labor over the subsequent years of the project as represented by this exhibit.

737 For "Maintenance Material" the amounts represent the cost of all material entering into the proper maintenance of the pipeline system, such as material for the construction of erosion dams, repairs to fences, repairs to roads, repairs to back fill, repairs to valves and fittings, repairs to pipe, repairs to couplings, and all material costs entering into maintenance of any part of the pipeline system.

The term of "Car and Truck" shows amounts to be expended in the operation of the company for automotive equipment, including trucks, teams and wagons, or any items of transportation that will be required in connection with the maintenance program.

The item of "Meters and Regulators" includes the maintenance labor and material for the maintenance of the meters and regulators as they become worn and deteriorate over the years 1939 to 1954, inclusive.

Through inadvertence in typing, there is no page 6 in this exhibit.

The recapitulation on page 7 includes the amounts shown on pages 8 to 14, inclusive.

The figures set forth on pages 7 to 12, inclusive, concerning operation and maintenance in Districts 3 to 6, inclusive, were determined in the same way as I determined the operating and maintenance costs of District 2.

This recapitulation on page 7 includes the operation and maintenance of the branch lines shown on page 13 and the

Joliet meter and regulator stations shown on page 14, as well as on pages 8 to 12, inclusive.

I arrived at the cost of operation and maintenance of the pipeline of Natural Gas Pipeline Company, Districts 3 to 6, inclusive, in the same manner as I have described in connection with the operation and maintenance of District 2 of Texoma Natural Gas Company, about which I have testified in detail and which is shown on page 5 of Exhibit 110.

It is my considered judgment, based on my experience as I have stated it, upon my knowledge of the pipeline, machinery, equipment and other property of defendants, of the demands upon the same in the course of each defendant's operations and the physical conditions existing along the course of each of the companies' pipeline and property, that, at the prevailing costs of labor and material as of June 1, 1939, as I have described, and at the unit costs which I used and which I have described in my testimony, these amounts set forth at the respective dates shown in Exhibit 110 will be expended by defendants in the operation and maintenance of their properties.

(Exhibit 110 was offered in evidence.)

I stated that in so far as gathering lines of Texoma
738 Natural Gas Company are concerned, I used the average of 1936 to 1938, inclusive, in determining unit costs and applied those costs to the future expenditures for operation and maintenance of the gathering lines of Texoma, which costs I stated were about the same or less than the prices as they existed on June 1, 1939; but so far as the balance of the operation and maintenance of the properties of defendants are concerned I used the prices that were in existence on June 1, 1939.

When I stated that in my judgment the figures shown in Exhibit 110 would be expended as set forth therein, I was referring to unit costs in those places where I actually used unit costs in my testimony. I was using the prices as of June 1, 1939 as to future property in accordance with my testimony.

(EXHIBIT 110 was received in evidence over the objection of counsel for each of the two Commissions, who were allowed an exception.)

Cross-Examination Interposed by Mr. Slaff.

The figure for labor and maintenance expense shown on page 7 of Exhibit 110 includes labor cost incurred in the retirement of the property.

The item of $144,613 for material cost in 1936, shown in Line 9, is substantially different from such costs for the years 1935 and 1937. This is due to the fact that in addition to the regular maintenance expense that item includes material used in reconditioning and relaying the Cimarron River crossing, and reconstructing, reconditioning and relaying 12,545 feet of 12 inch pipe and 3,636 feet of 24 inch line and installing 294 chance anchors, and replacing of the 24 inch line with two 18 inch lines in Silver Creek. That is the cost of the reclaim or retirement, including both labor and material used in the connection. It would include the cost of the material used in the reclaim or the retirement of the 24 inch line and the lowering of two 18 inch lines across the North Skunk River. Those are the items which go to make that up. There may be additional items for which I do not have the details here. That is something that would have to be taken from the accounting records of the company.

Those are the items a statement of which is contained along with a statement of other items on page 18 of Exhibit 105, and those items, as I have stated, were charged to maintenance expense rather than to fixed capital. Our maintenance expense, labor and material, for the year 1938 includes some $42,000 expense incurred in connection with the Sheffield break of which I spoke this morning.

Direct Examination by Mr. Hedrick.

When I stated that the items which I have mentioned are
included in the expenditure of $144,613.02 in 1936 for
739 maintenance material in response to Mr. Slaff's question as to whether all the items on page 18 of Exhibit 105 were maintenance, I meant that only those items which I mentioned were charged to maintenance.

The other items on page 18 were expenditures direct to capital investment for additions to the physical property which did not exist prior to that expenditure.

The total amount shown on page 18 for work on river lines and loop lines for defendants is approximately $1,008,110, and of that amount approximately $206,820 was charged to maintenance material and labor. The difference, approximately $801,289, was charged to capital investment.

Cross-Examination Interposed by Mr. Slaff.

The expense of retiring the old line is charged to maintenance and that is all that was charged to maintenance expense in connection with that item.

I testified in a lawsuit to which Mr. E. V. Kesinger referred in his testimony, at Tulsa, Oklahoma, Henry L. Lemons *vs.* Natural Gas Pipeline Company of America. I also testified in a damage suit referred to by Mr. W. H. Davidson, in the County Court at Joliet, Illinois. I have not testified in any rate case before coming with defendant.

740 W. T. BULLA, a witness for defendants, testified:

Direct Examination by Mr. Hedrick.

(August 2, 1939.)

My name is W. T. Bulla. I live at Western Springs, Illinois. I am 44 years old.

My grammar school education and business school course, including telegraphy, was completed in 1911, at Parsons, Kansas, after which I completed a number of home study courses covering communication engineering, mostly courses of the American Telephone and Telegraph Company.

From September 1, 1911, until August 1, 1917, I was employed by the Missouri and Kansas Telephone Company, which later became known as Southwestern Bell Telephone Company, in various capacities. I worked as a line man for a little over a year in Parsons, Kansas; as construction clerk and telegraph operator at Joplin, Missouri, for approximately one year; as wire chief in charge of plant facilities at Chanute, Kansas, for approximately two and one-half years; and as toll tester, handling special circuits, at Kansas City, Missouri, for a little over one year. During my employment with this Bell system company I had the opportunity to gain experience in several phases of communication service.

From August, 1917, until June 1, 1930, I was employed by the Empire Companies, with headquarters in Bartlesville, Oklahoma, in the telephone and telegraph department, six years of which I was in charge of telephone and telegraph operations, carrying the title of wire chief; and four years of which I was assistant superintendent of telephone and telegraph, during which time I had general supervision of operation and maintenance as well as a number of construction projects; and three years of which I was superintendent of telephone and telegraph.

During my service with the Empire Companies I continued my experience in operation and maintenance and also supervised the construction of several hundred miles of pole and wire facilities in Kansas, Oklahoma and Texas.

Between January and the latter part of April, 1930, I covered the territory between Amarillo, Texas, and Chicago, Illinois, some of it the second time, to secure data, on the request of Mr. E. V. Kesinger, with which to make a recommendation for a communication system for the proposed gas pipeline, which is now the property of Texoma Natural Gas Company and Natural Gas Pipeline Company of America. This information was transmitted to Mr. Kesinger, Mr. Floyd C. Brown and others at conferences held in Bartlesville, Oklahoma, New York City and Kansas City.

From June 1, 1930, until July 1, 1931, I was employed by the Continental Construction Corporation, the name which has been changed to Natural Gas Pipeline Company of America. My duties were to supervise the construction of the communication system as it now exists. 741 I am designated superintendent of telephone and gas dispatching.

As the supervisor in charge of gas dispatching I have a group of dispatchers under my supervision, one of whom is on duty at all times. By that, I mean 24 hours per day in the Chicago office, to coordinate the activities of the various departments of these companies in so far as delivery of gas is concerned through the system, and to issue orders pertaining to the operation of this system in accordance with the instructions and policy outlined to them.

It comes within my jurisdiction and is my responsibility to give orders through these dispatchers covering the operation of gas compressor stations, the number of engines to be operated, and the speed at which these units are to run; also to give orders or authorization prior to the opening or closing of any valves or gates that can affect in any way our ability to deliver the maximum rated capacity of this gas pipeline. We necessarily contact each of the ten compressor stations, and also the Joliet measuring station, each hour of each day and night.

If, for instance, Mr. Strong, superintendent of the pipeline department, should wish to close a pipeline gate and shut out the flow of gas in order to make a repair to the pipeline, he is required to obtain authorization from me to close that gate. That is the common practice of the company. If Mr. W. H. Davidson or Mr. Powers should wish to shut down an engine, outside of an emergency, the operator of the station would have to obtain an authorization from me before shutting it down.

To facilitate our work, we have a company owned communication system over which we are able to contact the various departments and operators and over which we dispatchers have right of way. The set-up in general might be compared to the train dispatching system of a railroad. To function properly in my work I must have, and I do have, contact with various utility customers to whom we sell gas in order that I may ascertain the quantity of gas that they require, so that, if gas is offered to a customer and he is unable to use it, I may endeavor to sell it to some customer who is in position to use it.

For the same reason as previously given, the dispatcher must authorize the shutting down of a compressor station when the operators desire to do repair work on equipment, such as the cooling system. In fact, the operating departments and the construction departments must cooperate to the fullest extent so that we may plan considerably in advance any work that is contemplated, so that it will occur at a time when we anticipate the requirements of the utility customer to be the lowest, or at a time when the curtailment to these utilities will have the least effect. Plans are made months in advance for most of such work. When I refer to utility customers, I refer to any customer with whom we have a contract to deliver gas.

Several months ago, Mr. R. G. Strong, superintendent of pipelines, advised me of work on the 24 inch main line
742 which his department would like to do during the summer of 1939, stating that sections of pipe or main line gates were to be replaced due to faults found. Also Mr. R. T. Powers and Mr. W. H. Davidson, in charge of compressor stations, advised of work at various compressor stations under their jurisdiction, all of which would re-

quire shutting out sections of main line or being unable to operate certain compressor stations for a few hours while the work was being completed.

Having this data I was then able to contact our utility customers and secure their estimates for periods when we might expect their gas requirements to be less than normal, or when they felt that curtailments to them would be the least harmful, and with this information I was then in a position to work out a program with the other departments for the work contemplated.

It is with a great deal of satisfaction that we find on consulting a calendar such holiday periods as we had, combining the weekend and July 4th into a three-day period when customer utility requirements would be at a low ebb. A great deal of work both on the pipeline and at compressor stations was accomplished at this time. The same will be true for the weekend of September 2nd, 3rd, and Labor Day on the 4th. Such periods allow us to complete the work scheduled and to get the line pack back to a condition where we can again make normal deliveries to our customers.

The most recent work on the line or stations was on Sunday, July 23, and Sunday, July 30. The work on July 23 as scheduled included work on the pipeline and also some work at compressor stations. Authority had been granted for a certain maximum period of time in which to do the work. The Chicago District Pipeline Company and other utilities had been advised in advance that the quantity of gas available to them would be 25 million less than what was normally offered them on each of two days in which the work occurred. I say two days, because although the work was done during the daylight period of one day, that affects what to us are two days, inasmuch as our contract day starts at 12 o'clock noon.

Compressor Station No. 6 was one of the stations involved, and they were engaged in cleaning their cooling system, taking advantage of the fact that the pipeline was shut out just east of Compressor Station No. 8. They had been authorized to be inoperative for the same period of time, which was deemed necessary for the pipeline work.

However, as mentioned by Mr. W. H. Davidson, a lack of water or water facilities caused a delay which has been felt, or which was felt, for the week following the work, inasmuch as we operated without our usual line pack and we found it necessary to limit some utility customers to quantities less than what we normally tendered them.

In the case of individual compressor stations being inoperative, the location of the station makes considerable difference in our ability to deliver. If Station No. 1 is down, our entire source of supply for the system is cut off.

However, Station No. 2 being down would necessarily
743 have a much less effect on immediate deliveries than
would Station No. 10.

I understand there are a number of jobs to come up in the future by the pipeline and compressor station departments which will require more or less curtailment in our sales during the time or following the time that such work occurs.

(Counsel for defendants handed to the reporter a small map entitled "Natural Gas Pipeline Company and Texoma Natural Gas Company, Telephone and Pipeline System," which, at the direction of the Examiner, was marked Exhibit 111 for identification.)

Exhibit 111 is a layout of the telephone communication system. It shows the relation between the communication system and the pipeline. The broken line indicates the general route of the pipeline, whereas the solid, or, I might say, the crooked line indicates the communication facilities.

This system is divided, in that that part of it south of the point indicated by the arrow in the corner of Nebraska is our own company owned pole line, whereas that part of it from that point east across Nebraska, Iowa and Illinois consists of company owned wires and necessary fixtures in place on other companies' poles, for the most part, with the exception that each of the branch lines has a portion of them on company owned poles. For instance, in Iowa, where the figures 7, 8 and 9 occur, and in Illinois where the figure 10 occurs, part of the line is on our poles and part on the poles of other companies.

I might best describe the wire facilities by saying that so far as the main line is concerned, it consists of a four wire system by which we derive three talking circuits, and it is possible to derive a number of telegraph circuits. In so far as we are concerned, we have only one telegraph circuit set up. This system, in general, is known as a magneto system. You might liken it in that respect to the farm lines. In other words, the telephones used are of the hand generator type which you crank to signal other stations or the operators. The circuits are metallic circuits. The conductivity is very high, and the transmission equivalents are good. It is likened to a long haul toll circuit of commercial telephone companies. We use telephone receivers, telephone ringing equipment which pick up weak signals and re-amplify them on, as is necessary on any long haul circuit.

(EXHIBIT 111 was offered and received in evidence without objection.)

Cross-Examination Interposed by Mr. Slaff.

On the main line, the pole line from just south of Station No. 6 up to Chicago is on the property of the C. B. & Q. Railroad. Some of the branch lines are on telephone company poles and some are owned by us.

744 *Direct Examination by Mr. Hedrick.*

From Station No. 6 to Chicago, the wires of the company are generally, so far as the main line is concerned, on the C. B. & Q. poles.

(Counsel for defendants handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Additional Capital Expenditures and Operation and Maintenance, Telephone Department, Witness W. T. Bulla," which, at the direction of the Examiner, was marked Exhibit 112 for identification.)

I am requested to refer to Exhibit 112, page 1, and, under the sub-heading "Additional Capital Expenditures," explain Line 1, entitled "Radio Communication Equipment," showing expenditures in 1940, 1943, 1945, 1948, and 1950, and state the necessity for those expenditures.

By referring to Exhibit 111 you will note that the route of the telephone line deviates somewhat from that of the pipeline, and we found it necessary in 1938 to secure certain radio equipment to use in addition to our other communication facilities so that communication might be provided whereby we could better coordinate our work, particularly in emergencies, so that line breaks or emergency work could be completed in the minimum time and thereby limit the loss in revenue due to decreased gas sales on account of breaks.

It is the general feeling that the north end of the pipeline system is the more important, the reason for this being that it is closer to the markets, so that if an interruption occurs due to a main line break it will affect the customer so much quicker that it behooves us to make repairs as quickly as possible on that end of the system, even more quickly than is required on the south end of the system.

We decided in the early part of 1938 that it would be helpful if we provided a limited amount of radio telephone equipment, and proceeded to secure licenses from the Federal Communication Commission, and purchased and installed the necessary equipment to so equip radio transmitting stations at each of Stations 6 to 10, inclusive. We had practically no difficulty in convincing the Federal Communication Commission of the necessity for the operation of these radio sets.

We also provided one additional set as a portable emergency unit. By that I mean a transmitter. We also provided receiving sets to go with each transmitter, also automobile type receiving sets similar to that used by law enforcement bodies, and after equipping a number of company cars and trucks, we were then in a position to broadcast information when emergencies occurred.

When an emergency occurs it behooves us to notify pipeline department supervisors, their crews, and others who may have receiving sets in their company cars as quickly as possible. With this equipment we are able to broadcast information when emergencies occur to give them the location, if it is known at that time or as soon as it
745 does become known, and thus to coordinate the work of getting men and material to the emergency as quickly as possible.

It was rather difficult to secure equipment for this particular purpose, due to the fact that the Federal Communication Commission placed certain limits on the type of equipment that can be operated by the class of operators which we can afford to provide and have the project be economical. What I am getting at is that these stations are limited in power, and to increase that power so that one large station might be used instead of several smaller power stations would require the constant service of operators so qualified that we would have to employ specialists for this duty, whereas with the type of equipment which we have secured we can use a limited amount of specialists, which, for the most part, we already had in our telephone organization, and with some home study courses and the passing of a somewhat easy Federal examination, we can take our regular employees, such as clerks, and qualify them to handle this equipment.

In 1938, as before stated, we purchased equipment costing $6,000. We have since that time been endeavoring to sell the management of our company on the idea of placing additional equipment on the south end of the system of Natural Gas Pipeline Company and on the system of Texoma Natural Gas Company. I am of the opinion at this time that they will allow that expenditure in 1940, and it has been set forth in that year to cost $8,000. We do not estimate the life of this equipment to be more than five years. Therefore, the same amount reoccurs in 1945 and in 1950, being replacements of the radio communication equipment to be purchased in 1940. The expenditure in 1943 will be to replace the radio equipment purchased in 1938, and the same also applies in 1948. The equipment to be purchased in 1940 is for a different group of locations, so that it would not necessarily be the same as that purchased in 1938.

I feel that the expenditure in 1938 for the north end of the line has been fully justified. The radio equipment has been instrumental in providing communication which facilitated the work previously mentioned on July 23rd and July 30th, in that it allowed one supervisor to keep in contact with several repair jobs that were in progress at the same time in various locations.

Counsel has inquired how we would communicate with the compressor stations or the Chicago office without the radio communication equipment if we had a shutdown or a break where the line crosses the Mississippi River between Iowa and Illinois, which is considerably removed from the telephone line.

We have already had an experience where supervisors and trucks were traveling along the highway when they were needed elsewhere on the system, and when information was broadcast to them that an emergency existed, giving them the location, they acknowledge the receipt of
the radio request within fifteen minutes of the time it
746 was broadcast. If it had not been for this means of
communication it would have been necessary to send a
messenger by car or to endeavor to intercept these employees at some point they might pass on their way to their destination.

I do not believe I answered the question I was asked about means of communication if we had occasion to call cars and trucks for an emergency existing over on the Mississippi River. Using the radio, we would be able to call those employees immediately, whereas if we did not have that, it would be necessary to send messengers to the locations where they were thought to be, telling them of this, which would cause considerable delay.

The operators are not able to get the base ball games on these radio receivers. So far as the transmitting equipment is concerned, we are definitely limited to a certain wave length and assignment of a certain kilocycle on which we can operate. We cannot operate on any other wave length. The receiving equipment is not quite the same. We have to convert it, but it is locked on one frequency. They cannot listen in to regular program broadcasts. It is impossible for them to do that.

As to how we would locate a man who had radio receiving equipment on his car, we know the car numbers. There is a car of a certain number assigned to that employee. We know that employee is driving that company car. If we wanted that individual we would call for car number so and so. An example of that would be if an employee working out of Station No. 10 was en route somewhere or working at some place on the system, the operator in charge of the transmitting equipment would go on the air, announce his call letters, and say that he was calling Car No. 350. "Calling Car 350," repeating that until he felt sure that the employee who had such car had heard it.

If he does not have his receiving equipment switch turned on, we do not have a device for notifying him to turn it on. We have experimented on some such plan; but we do not have anything in operation. Our present plan of operation is that on the half hour of each hour when an employee driving a car so equipped with a receiving set is out away from his headquarters, he will turn that set on for a reasonable period, say about five minutes, on the half hour of each hour, so that he might hear any information that might be sent out.

Cross-Examination Interposed by Mr. Slaff.

I believe it is true that the price of the equipment which I used as of June 1, 1939, speaking of radio equipment, is identical with the price of the equipment installed in 1938.

The prices of June 1, 1939, were used in determining the prices for the labor, material and equipment referred to in Exhibit 112, for the entire exhibit.

Line 2 is entitled "Voice Repeaters." These voice
747 repeaters are in reality voice amplifiers. In other
words, in talking out over the telephone circuit, after traveling a certain distance, the volume will be dissipated. We pick up the volume and repeat it or reamplify it, so that it will carry on in about the same volume at which it originated. We contemplate that it will be necessary to replace the existing voice repeaters, nine in number, in 1943, at a cost of $4,650. These voice-repeaters wear out so that they need replacement. They are rather delicate instruments, consisting of transformers, small relays with minute parts on them, and due to constant wear on these parts we anticipate it will be necessary to replace them entirely. It is our experience that they wear out within the period of time described by me. Those are Western Electric repeaters.

Line 3 is entitled "Ringing Equipment," and shows an expenditure in 1943. The ringing equipment as used on our communication system is somewhat similar to voice amplifiers, in that we pick up the ringing current when it becomes dissipated and resend it over the same cycles in an added volume so that it may be heard over long distances. This item is the replacement of the present existing signal equipment, which is also rather delicate equipment, and I anticipate that it will be necessary to replace it wholly in 1943, or prior to that date, on account of its wearing out. Most of the equipment was installed in 1931.

Line 4 is entitled "News Crossing Canadian River," and shows an expenditure of $3,000 in 1945. This is the Canadian River aerial telephone crossing on the part of the system of Texoma Natural Gas Company near Sanford, Texas. At the point where we cross, the span from fixture to fixture is some 2400 feet. It is very rocky and rugged country. Extreme winds are experienced there and we have had difficulty at or near the same location in previous years. This crossing has been replaced once since it was originally constructed, and we deem it necessary to replace this crossing again, probably before 1945. It is pretty much of a guess as to when it will be necessary, but I doubt if it will last any longer than 1945. The figure we have used for 1945 is equal to the figure that stands for our actual expenditure on the first replacement. If you will look at Item 11 on page 1, you will see that in 1946 we have the retirement of this crossing, which on our books is $2,792. We will retire it in 1946, the following year. We cannot retire that crossing until the new one is erected and ready for service.

The part of the crossing that wears out is principally the wire. The wind load, or ice load, when that exists, causes a continual flexing of that wire so that it will crystallize. That is principally at the points where it is tied in. However, we do not deem it advisable to splice that wire in the middle of the span or out in any part of the span. It is so difficult to erect those wires across that stream that we feel that we should put in new wire, and the old wire is taken away in such condition that it cannot be used. I think we would still have that flexing if we suspended the wire from a cable. We would have it in the cable then, as well.

Line 5 is entitled "New Lines Telephone Service—Skellytown," and shows an expenditure of $3,019 in 1942. Skellytown as referred to in this exhibit will be found on
748 Exhibit 101. We contemplate the construction of approximately five miles of pole line, with the necessary wires and pole facilities, to extend a telephone line from the present existing gathering system to a proposed camp to be established by the company in the vicinity of Skellytown, Texas, in 1942.

On Exhibit 101 the existing telephone lines are indicated by a solid green line. The proposed lines to be constructed are indicated by a broken green line. The proposed camp site at Skellytown is in the northeastern part of Carson County. We propose to extend that line west from Skellytown a half mile and then south to the present telephone lines.

The proposed booster stations in the southwest part of Moore County will have as a central location a booster station known as M-26, which will be located in Section 29, Block P.Mc., E.L.R.R. Survey, in Moore County, Texas. The expenditure in 1945 of $4,472 for new telephone service at Kilgore is to extend communication service to those points where it is felt it is needed.

Page 1 of Exhibit 112 shows the book cost of equipment retired in connection with the additional capital expenditures shown on that sheet.

You ask me to refer to Line 2 under "Additional Capital Expenditures," which shows $4,650 expenditure, and Line 9, under "Book Cost of Equipment Retired," which shows an amount of $2,694, and explain the difference in those two items.

At the time this equipment was placed in service, the only reliable source of supply was the American Telephone and Telegraph Company, which had these items of equipment manufactured for their use or for leasing to customers, where they approved of the use of such equipment, so that for a number of years we secured the use of this equipment on a rental basis. However, after we used this equipment for a few years it became the policy of the American Telephone and Telegraph Company to sell such equipment to us and to give us certain credits for rental which had been paid on this equipment, which would be applied to the purchase price. That is the reason why the retirement cost is less than the purchase of new equipment. It is my judgment that the equipment cost about the same money, or probably more, at the time we started leasing it.

Cross-Examination Interposed by Mr. Slaff.

I do not have the definite date when the change-over was made from a leasing policy to an outright sales policy. It occurs to me that it was about 1936 or 1937. I could determine that, but I do not have it. That was the A.T. & T. itself.

Direct Examination by Mr. Hedrick.

I have broken down the additional capital expenditures
of the telephone department on pages 3 and 4 of Ex-
749 hibit 112, page 3 being the additional capital expendi-
tures of Texoma Natural Gas Company and page 4
being additional capital expenditures of Natural Gas Pipe-
line Company of America, and the totals of the two pages
are shown on page 1, from which I have just testified.

I am asked to refer to page 2 of Exhibit 112, entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company. Telephone Department. Operation and Maintenance," and under the heading "Operation" where the first line is entitled "Labor," and to explain how I arrived at the various amounts set out in that line from 1939 to 1954, inclusive. By using the average of the years 1936 to 1938, inclusive, I determined what the actual expense had been, and knowing the contemplated changes or additions to labor for operation, I was able to project the amounts as shown for the years 1939 to 1954, inclusive. With reference to both operation and maintenance labor shown on page 2, it is my judgment that the cost of those two items will increase somewhat in the years to come.

As to how I arrived at the amounts set opposite Line 2, entitled "Material," on page 2 of Exhibit 112, having the benefit of the record of previous expenses, I was able to project the amounts as shown for the years 1939 to 1954, inclusive, in the same manner as I determined the operation labor.

Line 4 indicates traveling expense of the superintendent of telephone when covering the system supervising operation and maintenance, and in my judgment this expense will materially increase over the average of 1936 to 1938, inclusive, due to the additional time and expense that will be incurred in traveling from point to point to determine work to be done. By this I mean work to be done on our communications system.

Line 5, "Leased Facilities," covers the rentals paid for the use of leased communication circuits, telephone, telegraph, repeaters, and miscellaneous telephone relays, and the principal items are such leased facilities as we have with the C. B. & Q. Railroad Company, where we pay an amount for the privilege of space on their poles and cross arms for our wires.

I arrive at the amount involved by having the benefit of previous costs chargeable to this item, and anticipating that certain rates would be increased or certain additional facilities would be required on which we would pay rental. I might say that we are operating on a contract with the C. B. & Q. Railroad Company which expires in 1945, after which I do not know what the rate will be that we will be required to pay this company for this privilege. We do know that the rate we are now paying, and have been paying, is a rate that is used quite generally by commercial companies to lease space. If anything, it would be my judgment that this rate might be increased, in which case the figures which I have projected will be too low.

Inasmuch as there are no other main pole lines following the general route of our pipeline, if we should be unable to secure a further contract with the C. B. & Q. Railroad 750 Company, it would probably be necessary that we construct outright a pole line of our own, and a rough estimate of that cost would be in the neighborhood of $1,000,000. At the moment I do not anticipate any difficulty in renewing that contract; but I do not know what the attitude of the railroad company is, inasmuch as I have not consulted them.

Leased circuits from the regular telephone companies would cost a prohibitive amount. With the commercial telephone companies, the practice is to charge for channels rather than physical circuits. In our case, where we string four wires and derive three talking circuits and one or more telegraph circuits, they would not allow such a condition to exist under one of their rental agreements. It would be necessary that we pay for each talking circuit and for each telegraph circuit, and it is my opinion that that would cost double the $32,200 which I have listed as the cost of leased facilities.

Cross-Examination Interposed by Mr. Slaff.

It is true that in that case they would have the burden of capital investment involved which we now have for such wires, poles and so forth.

Direct Examination by Mr. Hedrick.

Our maintenance labor as shown in Line 7 covers the salaries of linemen, groundmen, helpers and other laborers used in maintaining and repairing telephone lines. The average of 1936 to 1938 for those items is materially increased in and after 1939. The reason for that is that our pole line facilities are becoming older, requiring a greater amount of maintenance. As poles become older they will deteriorate, breaking off, causing excess trouble, which will require that we not only clear the trouble, which is an added expense, but also that we use more men, put in more hours, in endeavoring to repair these poles and wires and keep them in an operative condition.

That is partially responsible for the increased cost in 1938 over 1937. Also, in the spring of 1938 we suffered a severe sleet storm which demoralized communication facilities of our company and all commercial companies between the western part of Illinois and central Kansas.

The principal part of the poles in our system are basically 20 foot poles, with a 5 inch top. That is to most people who erect poles a very small pole. Naturally, the circumference at the ground line is small, and although they are treated poles, the rotting condition, the deterioration, will cause the strength of those poles to deteriorate so that the cost of replacing the poles will be much greater as they become older. They are completely treated poles.

The explanation I have given for maintenance labor is about the same explanation I would give for the cost of maintenance material, shown on Line 8 of page 2 of Exhibit 112. I might amplify that by reminding you that
751 basically our pole line consists of 20 foot poles. They cannot be cut off and reset. The amount of clearance that you derive between the surface of the ground and your wires is so small that you cannot follow the practice of cutting off and resetting, as generally practiced by telephone companies.

We use cross arms except on the gathering system, where there are only two wires, and there we use a bracket. We use one cross arm for a pole except at angle points, where we use two cross arms as a matter of safety.

Line 9, covering car and truck expense, covers gasoline, oil, tires, and so forth, for company cars and trucks, and covers hired cars, trucks and teams necessary to provide transportation for linemen and others who have occasion to maintain the telephone system. It is based on information we have as to previous costs, also anticipating that our cost for transportation will increase as we use additional men in maintaining these lines, and in 1946 or 1947 it will cover the additional expense of an additional car for this same purpose of maintaining the lines.

The information contained on page 2 of Exhibit 112 is broken down on pages 5 and 6 of the exhibit, so that on page 5 the operation and maintenance of the telephone department of Texoma Natural Gas Company is shown, and on page 6 the operation and maintenance of the telephone department of Natural Gas Pipeline Company of America is shown. These two sheets merely divide the expense so as to show each company separately. The totals of pages 5 and 6 are shown on page 2, about which I have been testifying.

Cross-Examination Interposed by Mr. Slaff.

In the replacement of poles the labor is charged to "Labor", as shown here on Line 7, and the material is shown under "Material" on Line 8. It is charged to maintenance expense rather than as an addition to the capital account. The same would apply to cross arms, anchors, guys, and all equipment in connection with the pole line. The only time that it might be different is if due to some local condition we had to re-route a line or build an additional mile or two, we would put that under capital.

If it is necessary to replace a pole, the new pole is charged in here as indicated on Line 8. The old pole is taken out of service. Any labor involved in either putting in the new pole or taking out the old pole will be charged to "Labor" as on Line 7. No credit is made to fixed capital for the pole which is taken out of service, and neither is there a charge for the new pole. The charge is made to maintenance expense of the pole which was installed, and no credit is made to fixed capital. We still have one pole. We charge to maintenance the expense of removing the pole which is taken out of service.

Direct Examination by Mr. Hedrick.

It is my considered judgment, based on the experi-
752 ence I have stated, upon my knowledge of the telephone system and other property under my supervision, concerning which I have testified, the demand upon this property in the course of each company's operations, and upon the conditions which exist along the line with regard to weather particularly, that, at the prevailing cost of labor and material as of June 1, 1939, the amounts set forth in Exhibit 112 will be expended by defendants for additional capital expenditures and in the operation and the maintenance of the telephone department property on or before the respective dates set forth in Exhibit 112.

(EXHIBIT 112 was offered and received in evidence over the objection of counsel for each of the two Commissions, to whom an exception was allowed. Motion by Commission Counsel to strike testimony of Mr. Bulla denied.)

Cross-Examination by Mr. Slaff.

I have not testified in any other cases.

753 **S. E. CAMPBELL, a witness for defendants, testified:**

Direct Examination by Mr. Morgan.

(August 2, 1939.)

My name is S. E. Campbell. I live in Kenilworth, Illinois. I am secretary and assistant treasurer of Texoma Natural Gas Company and Natural Gas Pipeline Company of America. I have been in the employment of these two companies since they originated in 1930.

I graduated from the University of Kansas with a B.S. degree in mechanical engineering, and immediately after that I joined the employment of the Cities Service Company in what is known as the Empire Companies at Bartlesville, Oklahoma. That was in July, 1916. I was first an engineer in what they term their junior engineering course. Shortly after that I was taken off the course and placed on the construction and operation of a gasoline plant at Caney, Kansas. I was later superintendent of that plant until May, 1917, when I was transferred, as assistant to the construction engineer, to Okmulgee on the construction of a cracking plant.

From there I joined the army and was in the army until July of 1919, when I returned to the employment of the Empire Companies at Bartlesville, as an engineer. Shortly after that I was placed in charge of their estimating department in the engineering and construction division, and had charge of preparing all their construction estimates.

In 1922, as I recall it, I was made chief clerk of the engineering division, having charge of all of the office personnel and all of the field accounting in connection with the construction work of that engineering division.

In 1926 I was taken off that work and placed in charge of the design and construction of compressor stations and gasoline plants. In 1928 I was made assistant purchasing agent for the Empire Companies, in which position I remained until I joined the Continental Construction Corporation on this Chicago project in the capacity of assistant chief engineer under Mr. Kesinger, the chief engineer.

When the line was completed and put in operation I was assigned the position of superintendent of operations of both Texoma Natural Gas Company and Natural Gas Pipeline Company of America, which position I occupied until

December, 1933, when I took over the duties of the secretary's office. I was assistant secretary for a short period of time, and later, in 1934, I was made secretary and assistant treasurer.

As secretary of these two companies, I have general supervision of the accounting work of the companies. I have the custody of the records of these companies and their books of account, and the accounting personnel perform their duties under my direction.

754 I caused my personnel to give to Mr. Strong and the other operating heads the figures carried into their respective exhibits as book cost of retirements of capital items which they testified would have to be retired from service from time to time during future years. Those figures were taken directly from the books and represent the cost of those items as reflected by the books. I have examined and am familiar with all those exhibits.

In addition to the books of account and the records of the company, I have in my custody the furniture and fixtures for the entire Chicago office and field offices of both defendants. We keep a record of where all this material is, and the field office or other office using this material reports to us its condition. We pass on whether it should be repaired or overhauled or replaced. As a matter of fact, no article of furniture or equipment of any kind can be purchased until I say so.

I have made a study of the future requirements of these two companies for office furniture and fixtures in the various offices maintained by the two companies over their system. This equipment consists principally of desks, tables, chairs, files, drafting room files, or files for maps of the larger type, typewriters, calculators, adding machines, comptometers, duplicators, ditto machines, and, in the Chicago office, water coolers. We find that the mechanical equipment needs replacement periodically. By mechanical equipment I mean such items as adding machines, calculators, comptometers, typewriters, duplicators, drinking fountains, ditto machines, and we also include law books in that category. Some law books become obsolete periodically, and are replaced by later editions, and we consider that a replacement item.

(Counsel presented the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Additional Capital Expenditures, Furniture and Fixtures," which document, at the direction of the Examiner, was marked Exhibit 113 for identification.)

Exhibit 113 reflects the additional furniture and fixtures that will be required by defendants from 1939 to 1954. It also reflects the replacements of the necessary furniture and fixtures for the same period of time. It reflects the book cost of furniture and fixtures retired and the salvage of the equipment replaced.

Page 1 of this exhibit is a recapitulation of the additional furniture and fixtures, replacement of furniture and fixtures, book cost of property retired, and salvage, for both Natural Gas Pipeline Company of America and Texoma Natural Gas Company combined, for the years 1939 to 1954, inclusive.

Page 2 shows in detail for Natural Gas Pipeline Company only, the additional furniture and fixtures, replacement of furniture and fixtures, book cost of property retired, and salvage.

755 Page 3 represents the same type of detail as page 2 except it is for Texoma Natural Gas Company only.

On page 2 the first item, "Additional Furniture and Fixtures," followed by lines 2 to 5, inclusive, which have the sub-heads "Calculating Machine," "4-Drawer Filing Cabinets," "5-Drawer Map Filing Cabinets," "Law Books," refers to furniture and fixtures in addition to that which Natural Gas Pipeline Company now has. That is in addition to existing equipment, and is not to replace equipment now on hand.

The calculating machine, in the amount of $585 in 1939, has been purchased and is now in use.

The four-drawer filing cabinets are required in the executive offices and legal department for the filing of corporation records and legal files. Four of these will be required in 1939, and two each in 1940, 1942, 1944, 1946, 1948, 1950 and 1952. The purpose of these files is to take care of the normal growth or increase in the volume of the papers that are put in those files, assuming the normal operations of the company.

The next item, Line 4, referring to 5-drawer map filing cabinets, is to take care of the additional maps in our drafting department in the Chicago office. One of these will be required in 1939, one in 1943, one in 1948, and another in 1953. Those files are to take care of the normal accumulation of maps and other records which are filed away.

The next item, Line 5, entitled "Law Books," is to take care of our additional requirements in our legal department. This item is for the most part an annual service which costs $720 per year. That will be necessary in each of the years from 1939 to 1953, inclusive. That covers the cost of the current bound volumes of the reporter systems that are contained in our legal library. It covers also the text books and other current books that are added to the library each year. This is all in line with our past experience and our present budget.

The item "Replacement of Furniture and Fixtures," the second sub-heading, followed by Lines 8 to 13, inclusive, captioned as shown here in the exhibit, refers to replacement of furniture and fixtures that have become worn out and unserviceable. It does not embrace desks and things that will be used indefinitely, but deals particularly with mechanical equipment.

The first item is "Adding Machines." We have computed the number of machines that will be replaced each year on the basis of our past experience as to the life of these machines and the number of them we have on hand. Two are scheduled to be replaced in 1939 and each of the years following, at a cost of $848 for two machines. This schedule shows the time when those machines will have arrived at the end of their useful lives based on the experience we have already had with that character of equipment and the number of machines which we have in service. This item does not provide for an increase in the number of adding machines at all.

756 The next item shown, Line 9, under the caption "Calculators," provides for replacements likewise on the basis of our past experience as to the life of the machine. Two of these machines will be replaced in 1939; one in 1941, 1942 and 1943, respectively; two in 1945; and one in each of the years 1946, 1947, 1949, 1950, 1951 and 1953.

The next item, Line 10, "Comptometers," is likewise based on their average useful life from our own past history. One will be replaced in 1939, two in 1940, one in 1941, two in 1942, and one in 1943, and so on, as indicated here on the exhibit. I will not repeat the detail.

The next item is "Typewriters." The replacement of typewriters is likewise based on the company's past experience as to the useful life of this equipment. We will replace five in 1939, three of which, I believe, have already been replaced; five in 1940; six in 1941, and so on throughout as shown, to the year 1953.

The next item is a duplicator which we use to run copies from stencils. It was replaced in 1938. We feel that it will have to be replaced again not later than 1946, and at a cost of $500.

Line 13 refers to drinking fountains. They are the General Electric type, and we have three of them in the Chicago office, one of which was replaced in 1937, one in 1938, and a third will be replaced in 1940. These three machines will again be replaced in 1945, 1946 and 1950, respectively, at a cost of $225 each of those three years.

The next sub-heading is "Book Cost of Property Retired." That refers to the mechanical equipment which I have just testified to under the sub-heading "Replacement of Furniture and Fixtures." Those are the items to be replaced by the items under the sub-caption just mentioned. The amounts set opposite the various items under this caption were taken from the books so far as the items which we now have are concerned. There is an item of $175 for law books under this caption. We have certain services that become obsolete from year to year and retire those services from our furniture and fixtures account. These services are commonly known among the lawyers as advance sheets. When the bound volume comes out the advance sheets are discarded.

The item of "Salvage" represents the trade-in value of the property retired as of June 1, 1939. When we trade in a typewriter or a calculator or a duplicator, or some of these mechanical items, we get an allowance for the old one. This is the schedule of allowances which we receive, assuming that they continue as they were on June 1, 1939.

Going back to the item of "Law Books" for just a moment, the $720 which is scheduled to be expended for law books each year includes the cost of the advance sheets which are discarded when the bound volume comes out.

We will pass now to page 3, which refers to the additional furniture and fixtures and the necessity for replacement of furniture and fixtures of Texoma Natural Gas Company. This refers to those items of equipment listed here which
will be required by Texoma Natural Gas Company at
757 its Amarillo office, Fritch office, the field office at Du-
mas, and the proposed field office at Skellytown. The items listed are directly in line with the drilling program to which Mr. Bussard and Mr. Dickinson have testified,

5

which will require additional personnel in the Amarillo office and in the Fritch office due to the extension of gathering lines, additional meters, the upkeep of those meters, and additional personnel at Dumas on account of additional gathering lines, requiring additional field foremen. At Skellytown there will be an office established due to the increased gathering system in that vicinity.

The equipment listed is based on the actual requirements of the personnel which will have to be added as the result of the drilling of additional wells and the building of additional gathering lines and the installation of booster stations, all of which we know is inevitable. It is applicable only to that type of personnel that requires office furniture.

In preparing this data I worked directly with Mr. Dickinson and Mr. Strong, as they are the only department heads that will require additional furniture and fixtures. This program is based on their requirements. In my judgment those amounts will be expended on or before the dates indicated here for such items.

Our calculations as to replacements of furniture and fixtures shown on this page have the same meaning as they did on the prior page. It is exactly the same type of equipment. This equipment wears out down there just the same as it does up here. In fact, it wears out more rapidly down there, due to the lack of service facilities and the bad dust conditions under which it has to operate. We have to replace it oftener.

The figures for adding machines, calculating machines, comptometers, typewriters and ditto machines, and so on, are based on the actual schedules for replacing equipment now in service and on the actual cost of that equipment as of June 1, 1939.

The figures under the caption "Book Cost of Property Retired" are arrived at in the same manner as were the figures under the same caption on page 2. The very same procedure was followed in this particular and also in the matter of salvage. The figures shown there represent the trade-in value as of June 1, 1939. All the figures shown here are based on prices as of the date last mentioned.

Cross-Examination Interposed by Mr. Slaff.

The cost figures for capital expenditures, for replacements, and for the trade-in allowances, are based on prices as of June 1, 1939. I am not talking about the book cost of the property retired. Those costs I have already stated are the actual costs of the articles to be replaced in so far as equipment is now on hand.

758 You ask how it happens that the figures for book cost of property retired coincide with the figures for replacement of furniture and fixtures, the latter being priced as of June 1, 1939 and the former being priced as of the time they were entered on the books of the company. That figure was pulled by the men in our department in charge of the books; and I assume the prices we paid on the equipment we now have are the same as the prices as of June 1, 1939.

Direct Examination by Mr. Morgan.

That would indicate that there has been no change in the prices of adding machines, calculators, comptometers, and so on, from the time we bought them to June 1, 1939. They have all been purchased in the last few years. Those that we originally bought were traded in and replaced some time ago.

(EXHIBIT 113 was offered and received in evidence over the objection of counsel for each of the two Commissions, to whom an exception was allowed. Motion to strike testimony of Mr. Campbell denied and exception noted.)

I have been somewhat familiar with the expenditures known as regulatory expense since 1937. I have made a study of the past and future requirements of defendants for that character of expense incident to regulation to which these companies may become subject. I have made a study of our past cost and have prepared an estimate of what in my judgment this cost will be in the future for both companies.

(Counsel for defendants produced a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Regulatory Expense," which, at the direction of the Examiner, was marked Exhibit 114 for identification.)

The figures shown in Exhibit 114 for the years 1937 and 1938 were taken directly from the company books and represent actual expenditures. In arriving at my estimates for the years 1939, 1940, an so on through the remaining life of defendants, or rather, down through the year 1950, I have consulted with my co-executives, the general manager, the general superintendent, the general counsel, and others, in an effort to arrive at the best estimate I could of the nature of the regulation to which we may be subjected and the probable cost in connection with such regulation.

At the present time the defendants are subject to regulation by several tribunals, namely, the Federal Power Commission, under the Natural Gas Act; the Securities & Exchange Commission, under the Public Utility Holding Company Act; the National Labor Relations Board, under the Wagner Act; the administrator of the Wage and Hour Act; and, in connection with our radio equipment, the Federal Communication Commission.

These are Federal bodies. We also have the Texas Railroad Commission, which has jurisdiction to some extent in the production and transportation of gas to the point
759 that it is necessary for us to carry on litigation. The Iowa State Commission has regulation of our pipeline only to the extent of the safety requirements. That is all of the state commissions, as far as I know, that have any jurisdiction requiring regulatory expense.

Our estimates of this expense for 1939 and subsequent years are merely our best judgment after consulting with the representatives of defendants as above stated. We have no past history other than 1937 and 1938 on which to base this judgment.

In the light of our expenditures for this year, including those that are already incurred and will necessarily be incurred in connection with the further proceedings in these cases in which this hearing is being held, and from what we can foresee in the future, we feel that $250,000 is a minimum expense this year for the two companies. 20% of that nature of expense is charged to Texoma and the remainder is defrayed by Natural Gas Pipeline Company. No part of these expenses was charged to Texoma in 1937 and 1938. The expenses in those years were incurred in connection with the intervention of Natural Gas Pipeline Company and Texoma in the case between the Illinois Commerce Commission and Chicago District Pipeline Company, which we considered entirely a pipeline matter. We did not charge any part of it to Texoma. Both companies are parties to the present proceeding and we have adopted the policy of apportioning the expense 80% and 20% as above stated. That apportionment applies throughout the remaining years covered by these estimates.

We have incurred no expense as yet in connection with the National Labor Relations Board or any of these other regulatory bodies which I have mentioned. Our expenses in connection with litigation with the Texas Railroad Commission were charged as straight legal expense at the time they were incurred. As a matter of fact, it was expense incurred in connection with the efforts made by the Texas Railroad Commission to regulate our production down there and is propertly chargeable as regulatory expense.

In the light of the consultations I have had with my associates and in the light of my study concerning the probable regulations to which we will be subjected, it is my judgment that these figures represent a reasonable estimate of the expenditures we will be required to make in connection with regulatory bodies.

(EXHIBIT 114 was offered and received in evidence over the objection of counsel for each of the two Commissions, who were allowed an exception. Motion by Commission Counsel and Counsel for Illinois Commerce Commission to strike testimony of Mr. Campbell relating to Exhibit 114 also denied.)

Cross-Examination Interposed by Mr. Slaff.

You ask me to explain the difference for the year 1938 between the figures shown on page 18 of Exhibit 15, put into evidence by Mr. Woodford, which totals $190,788.47 for regulatory expense for the year 1938, and my figure of $175,572.13 for that year. I will check that figure and furnish the explanation, if I can find it, through counsel tomorrow morning.

760 (The following day counsel, in open hearing, explained that the figures shown in Mr. Campbell's exhibit were taken from the books as of September 30, 1938, instead of December 31, 1938, and that the exhibit should be corrected to read: the second line, 1938, $190,788.47; the total to read as of the same amount; and the total at the bottom, 1937 to 1954, inclusive, should read $792,256.10 for Natural Gas Pipeline Company; and should read for both companies $932,256.10 instead of $917,039.76.)

Cross-Examination Interposed by Mr. Booth.

Our estimates include our judgment of what all regulatory expense will cost us in the years between 1940 and 1954. We have made no provision, however, for other rate cases than the existing rate case. They are just investigations and items of that nature.

Direct Examination by Mr. Morgan.

I have included in these figures my judgment of what the cost of all forms of regulation, all investigations to which we may be subjected, and things of that kind, will be. These estimates, as I have explained, are made in the absence of any history on which to base the figures.

Cross-Examination by Mr. Slaff.

I testified before the Internal Revenue Bureau on the subject of deductions for the determination of income tax for the year 1935 for Natural Gas Pipeline Company of America.

I also testified before the Securities & Exchange Commission in a case of the Texas Company, where they requested exemption from the Public Utility Holding Company Act.

I testified in a tax case between Natural Gas Pipeline Company of America and the State of Kansas on state income tax matters.

You ask for the dates of my testimony. I am not sure that I can give the date I testified before the Securities & Exchange Commission. I will furnish these dates through counsel tomorrow morning.

(Counsel, in open hearing, in compliance with the request with reference to the dates on which Mr. Campbell testified, made the following statement:

Mr. Campbell testified before the Securities & Exchange Commission in re the Texas Company application at Washington on May 8, 1936; and before the District Court of Shawnee County, Kansas, in a proceeding by the Kansas Tax Commission against Natural Gas Pipeline Company of America, at Topeka, Kansas, on March 28, 1938. He testified before the Bureau of Internal Revenue in a proceeding styled "Re Natural Gas Pipeline Company of America" on three occasions at Washington: October 1, 1937; October 12, 1938; and July 5, 1939.)

761 (August 3, 1939.)

(Counsel for defendants made the following statement to the Examiner:

At the time Mr. Kesinger was on the stand, Mr. Booth requested the names of the industrial customers furnished directly with natural gas by Natural Gas Pipeline Company. Mr. Kesinger has prepared this list and I will read it.

New Jersey Zinc Company, near Depue, Illinois, under a contract dated October 15, 1938, expiring October 28, 1939. Darby Petroleum Company, near Great Bend, Kansas, under a contract dated May 3, 1938, expiring May 3, 1940. Stanolind Pipeline Company, near Great Bend, Kansas, under a contract dated April 6, 1938, expiring April 8, 1940. Northern Gravel Company, near Muscatine, Iowa, under a contract dated August 24, 1936, terminable on thirty days' notice. Palmer Oil Corporation, near Great Bend, Kansas, under a contract dated February 7, 1938, expiring February 7, 1940.)

762 G. M. DAVIDSON, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 3, 1939.)

My name is G. M. Davidson. I live in the Village of Wilmette, Illinois. I am chief engineer and superintendent of operations for defendants, which position I have occupied since December, 1933. I have been employed by defendants since July 1, 1931. My first position was that of chief engineer, which position I have held since the beginning of my employment.

I am a graduate in mechanical engineering of Stanford University. I volunteered with the California National Guard in June, 1917, and was drafted into federal service in July, same year, and was overseas from October, 1917, until June, 1919. I served as a second lieutenant and later as a first lieutenant in an engineering regiment with the Rainbow Division. On returning from the army, I was occupied for a few months in a refrigerating plant. I joined the Empire Gas and Fuel Company, engineering department, in November, 1919, and remained with that company until coming with my present employers. From 1920 to 1923, I was field superintendent of a gasoline plant. From 1923 to 1931, I was respectively an engineer in charge of design for the engineering department, superintendent of construction, superintendent of operation, and the last three or four years I was the general superintendent in the division.

When I first came with defendants, I was not familiar with their pipeline system. It required some time for me to become completely familiar with all of the work that had been done. As chief engineer, I found myself largely occupied in engineering problems of the operating division. Although I was in charge of the engineering department I assumed the work that had not been completed by January 1, 1932 with reference to organizing the operating personnel and matters of that sort. There were many operating problems relating to organization. Since the companies were put in operation, I have had executive supervision of the operating deparments, which includes the communications department, pipeline department, compressor station division, pressure dispatching department; and I also have charge of the purchasing department and the engineering department. I have supervision of the operations at Fritch, of the Texoma gasoline plant and all other activities of that company, except those of the production department in the Panhandle field. Engineering activities are varied in nature and often involve matters of special problems relating to new construction or new economic studies of one character or another. I find that I have to keep up with advances in the industry. That is, I have found it advisable to do this. I think I have told you I work with Mr. Kesinger. The automotive equipment is one branch of our activities which is not delegated to any other operating head. The chief clerk and I keep track of all the automobiles, and have charge of replacements and additions. The purchase and replacements of automobiles, as well as all types of automotive transportation facilities. for both companies, come directly under my supervision. I recommend the purchase of new equipment, but it has to have Mr. Kesinger's endorsement before it is finally approved.

763 I have prepared a study showing the schedule of replacements of this automotive equipment and the probable requirements of the two companies for additional automotive equipment in future years. I don't believe that the exhibit indicates the amount of equipment that we now have in the system except indirectly in that it indicates that which is to be replaced.

(At this point, counsel for defendants handed the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Additional Capital Expenditures, Automotive Equipment, Witness—G. M. Davidson," and requested that it be marked for identification as Exhibit No. 115. At the direction of the Examiner, the document was so marked.)

I have before me Exhibit No. 115. Page 1 indicates in three general groups the additions that will be made to capital by reason of automotive equipment. The first group includes all automobiles which will be replaced. The second group on the same page indicates the amount of property retired; that is, the original cost of this equipment written from plant account. The final group is the salvage group for both companies. This really is the trade-in value of the equipment which we are retiring on the purchase of new equipment. This statement includes all additional equipment, whether it is a replacement or an addition to present facilities. The statement is a combined statement for the two companies.

Page 2 is the supporting detail for the recap submitted on page 1, and indicates the equipment which will be replaced and the equipment which will be added by Natural Gas Pipeline Company of America.

Page 3 is a comparable sheet for Texoma Natural Gas Company. These latter two pages indicate the number of units to be replaced and added, but do not indicate any amounts. Turning to the first sub-heading on page 2, referred to as "Chicago Office," you will note that in Lines 1 and 2 there is an R in brackets after these titles. This indicates a replacement of original equipment now on hand. From experience, we have found that these cars are most economically replaced at certain periods of time and mileage. There is a compromise between the two factors, and the replacement of the cars noted in all of the items followed by this bracketed R is based on an experience table. In the light of that experience, we have adopted a definite policy with reference to the time of replacing this equipment. This statement is based on this policy and shows replacements at definite intervals throughout the life of the project, at which times the equipment will be replaced exactly on the basis of our past experience. All purchases following the bracketed R are to be replacements of equipment now in existence or equipment to be acquired hereafter.

Coming to Line 8, you will find that there will be some additional Chevrolet pick-up equipment being added to the

system and, following that through, you will note that there are five Chevrolet pick-ups to be added to all of our equipment in 1947. Following that notation in Line 9 you will find a replacement. The replacement in that instance is a replacement of the equipment which has been added to the system. In other words, on Line 9, the figure 5 under the caption 1949, refers to the same five Chevrolet pick-ups shown under the caption 1947 on Line 8. The necessity for the purchase of five additional Chevrolet pick-ups in the year 1947 I believe has been very well substantiated by Mr. Strong in his evidence. This is additional equipment which the superintendent of the pipe line system has determined will become necessary by reason of the additional requirements of personnel, such as requiring automobiles for added patrol service, and other added features, concerning which Mr. Strong has testified. There will be an added foreman, I believe, in
764 District No. 3 and another in District 4 and another in
5 West; another pick-up will be necessary in 5 East and another in District 6. These are for general maintenance and added maintenance which will be necessary by that time. I concur, without qualification, in Mr. Strong's judgment.

These other items down to Line 12 have to do with replacements of existing equipment and are subject to the same explanation made with reference to Items 1 to 7, inclusive. Item 12 is a reflection of our required added maintenance costs by the addition of two International five ton trucks in 1943 and two in 1947. The same explanation which I have made with reference to the added equipment noted in Line 8 explains these requirements for added equipment. I have considered the subject of this added equipment in detail with Mr. Strong and I am in full accord with his judgment. Line 13 is subject to the same explanation as Line 9.

In the normal operation of truck equipment on the pipeline, it is necessary to furnish trucks with a semi-trailer or occasionally a complete four-wheel trailer for hauling pipe. When we buy an additional truck, it is necessary to supply the trailer that accompanies it. That item is set out in Line 15. The equipment there shown will be acquired in the year 1948. The reason for supplying the additional truck explains the necessity for the additional trailer and we have arrived at the necessity for this additional equipment in consultation with Mr. Strong in the same manner as stated with reference to equipment already discussed.

Line 17 reflects the replacement of ten light tractors now in use on our system. These tractors are used in emergency work and for rather heavy maintenance, requiring the service of a winch somewhat more substantial than that which we have on our trucks. There are nine of these tractors on the pipeline properties and one on the Texoma properties.

Tractors are used for erosion control where we have to move a lot of dirt. We have in the field what are termed tumble bugs accompanying these tractors for moving the dirt; that is, they scoop up about a yard of dirt at a time and haul it and dump it in another location to refill, dams and things of that character. We have a definite policy with reference to trading in and replacing this type of equipment, as in the case of automobiles, trucks and trailers. That equipment will be replaced as indicated on Line 17, three in 1945, three in 1946, and three in 1947. In addition to the uses already mentioned, these trucks are used quite extensively in emergency repair work. We depend on the tractor for getting over the ground that the truck could not get around on at all. We have had some experience with that. All of these tractors have proven invaluable in an emergency of that character, particularly where it is wet and soggy.

On Line 18 is shown a R-4 tractor. This is a little heavier type of equipment than No. 22, noted in Line 17. We know from our experience with these light tractors that we can justify a heavier tractor for some of the work which they are doing, and that is reflected in the additional equipment on Line 18.

765 Our analysis and study of the future requirements discloses that we will require additional Caterpillar tractor equipment in the years 1943 and 1947. We know definitely we are going to have a heavier maintenance program. We believe that the use of the tractor equipment will facilitate the use of trucking equipment to an economical degree. We can justify a tractor over a truck in many heavier items of maintenance. It is our purpose to add larger tractors at the time we make these additional purchases. The same situation is reflected in Lines 19, 20 and 21, and the same explanation applies to these items. These few items of additional equipment set forth here have all been carefully considered and studied with the operating

head, Mr. Strong, and I concur in the latter's judgment as to the necessity for these items. In fact, I go further than that. We ~~have~~ had requests already from the field for this heavier type of equipment. It is being delayed on account of heavier maintenance. In other words, I am already convinced that it will have to be provided but feel justified in deferring it.

There is no additional equipment contemplated for the compressor station department. It has one car now stationed at each one of these plants and we believe that it is sufficient for all time. This program contemplates the replacement of that car at such time as the mileage and condition of the car indicates that it is due for replacement. This is in line with our fixed policy.

Under the telephone department, there are three lines, "Chevrolet Coupe, Additional and Replacement". In this department, we are replacing the equipment in line with our established policy. An additional car is required in that department largely due to the fair wage and hour law. This is a department which only has six active field men and we are already experiencing some difficulty in getting emergency work done because of the forty-four hour week limit. I know that we will have to give this department an additional man next year when our weekly limit will become forty-two hours of work. Line 26 shows the replacement of that additional car which is noted in Line 25.

The telephone cars are subject to a great deal more mileage service than some of the other cars. These boys put mileage on their cars that averages, I would say, about twenty-five hundred miles a month, and it is not unusual to find it up to three thousand miles a month. I believe that is the explanation for not having a replacement in 1941, having a replacement in 1942 and in 1943 of that car, skipping a year and replacing it, skipping it another year and replacing it, replacing it in 1948 and 1949 and having two replacements in 1950, 1952 and 1953. It is due to the factor of mileage as well as time entering into the future use of these cars.

Questions by the Examiner.

The description of the automobiles set up in Items 4 and 5 is not stated in detail. I have the description by passenger cars. We have in operation ninety-one units on both companies. Of these there are forty-three light passenger cars, Chevrolet sedans and coupes. We have eighteen Chevrolet pick-ups, thirteen trucks, seven large passenger cars, ten tractors and, I believe, ten trailers, a trailer not being considered as a power unit. There might be twelve trailers.

Page 3 is quite comparable to page 2 in its explanation, that page applying to the equipment of Texoma Natural Gas Company. The items noted in here are the replacements and additions with respect to the cars on the gathering system and the pipeline. Page 4 is a continuation of page 3 by departments. The third page covers the gathering system and pipeline requirements and page 4 the production department, telephone department, compressor station, and gasoline plant.

Those additional units to be acquired in the future for Texoma have been determined in the same manner as have the additional units already referred to. I have consulted with the department heads working with me concerning the additions to and replacements of all department cars except those of the production department, and on these requirements I have consulted with Mr. Dickinson. I am in accord with these department heads as to the additional units that will be required by Texoma. These replacements will be made in pursuance of our already established policy as to replacements. As already stated, the summation of those pages is shown on page 1. Going back to the second subhead on page 1, the term "Book Cost of Property Retired" indicates the original cost of the equipment, which we are retiring from plant in the two properties. We have used the basis of cost of the automotive equipment referred to in this exhibit the price prevailing as of June 1, 1939.

Under the caption "Salvage Value", Lines 7, 8 and 9, on page 1 of the exhibit, is reflected the trade-in allowance which we have been able to obtain in replacing our equipment on both properties, and also for the combined system. The trade-in values used are those obtaining as of June 1, 1939.

We establish the figures for the trade-in value by reflecting what we have been able to obtain from the equipment traded in. We have been able to get considerably higher trade-in values than those indicated in the automobile industry's blue book. This is due, I believe, to the fact that we have found the economical point for trading in our equipment. There is a compromise between mileage and the age of the car, and we are getting the maximum economical benefit from the use of any piece of equipment and the maximum trade-in allowance when we replace it. General Motors have told us that we are operating our fleet as economically as any fleet operator that they are acquainted with.

There is one thing that I might add in explanation here. If you will follow through you will notice that cars are being replaced on Texoma's system more often than they are by Natural Gas Pipeline Company. That is largely a reflection of the condition under which the cars are operated in the Panhandle field where we lack good roads. There are some roads, of course, but most of the travel is done over that part of the field where we depend on pasture roads, with very few bridges, and it is necessary to gun the cars in crossing creeks. In fact, I have not been able to get the salvage values from cars traded in for Texoma that we have those traded in for Natural Gas Pipeline Company. We have had the experience of replacing motors entirely on account of the dust.

767 (EXHIBIT NO. 115 was then offered and received in evidence over the objection of counsel for both Commissions, for whom exceptions were noted at the direction of the Examiner. Motion to strike testimony also denied.)

Cross-Examination Interposed by Mr. Slaff.

Salvage value, as reflected in Exhibit No. 115, is based on our past experience on trade-in values. From trading in these cars we have had the experience of getting so many dollars in trading two or three cars. Now, we would expect to get the same trade-in value had we traded this car in on June 1, 1939. This is, in effect, the average of trade-in prices for the type of car under consideration.

Direct Examination by Mr. Morgan.

I have heard the testimony of Mr. Bussard, Mr. Kesinger and the various operating heads concerning the study that has been conducted over the past year and a half and more, concerning the future requirements for additional capital expenditures and capital expenditures to replace existing equipment, and for maintenance and for operation. I have had considerable to do with these studies. I would like to review some of the facts that pertain to this forecast which has been made. This work started in February, 1938. Mr. Kesinger outlined a program to us for forecasting our future operation, maintenance and capital requirements. We attempted to carry this to completion, while continuing our regular operating duties, by calling in men from the field who were closely associated with the actual work to be done. It was apparent along about the first of the year that we were not getting the results that Mr. Kesinger expected, and it was decided to relieve these operating heads from their normal operating duties, and have them devote their time exclusively to this estimate. Since that time I have been consulting with these men and coordinating the work of one department with another. My opinion has been asked in many instances, and I think I am very well acquainted with this whole estimate so far as the operating departments are concerned. I could not devote as much time to it as I would have liked, because it was incumbent on me to keep this pipeline going. We still have to operate. In addition to my consultations with the operating heads, Mr. Strong, Mr. Powers, Mr. Bulla and Mr. W. H. Davidson, I have consulted with other men who I think are qualified to give an opinion on whether these costs are justified or not. In addition, I have gone to the field and have tried to get the independent judgments of the boys actually on the job in many of these forecasts. I worked with the department heads on occasion and on some of the detail itself. On some of the major matters I would like to think that I contributed something toward a more substantial figure than would have been obtained otherwise.

Now, I have done considerable estimating in my time, but I have never had the problem of forecasting an expenditure to the degree that Mr. Kesinger was insisting on in this budget. The exacting character of this forecast, as originally outlined to me, led me to believe that it was going to be the greatest job of crystal gazing that any engineer ever had. As this thing has turned out, I sincerely believe it is a conservative estimate, far from being a boiler-house guess. By a boiler-house guess is meant, in
the vernacular of the oil field, a rather violent
768 assumption. You might appreciate it if I tell you
that a pumper on a lease in the middle of the winter
is inclined to stick pretty close to the boiler house, where

it is warm, and particularly if there is a lot of snow on the ground and a blizzard outside. He will open a crack of the boiler-house door and he will guess his production for the day, instead of going out and measuring it. Maybe you can sympathize with the boy, if he has to walk over a foot or a foot and a half of snow on an 80-acre lease; possibly he is justified in making a boiler-house guess then.

But this thing is far from being a boiler-house guess. It has received concurrence through a sifting process that has repeatedly gone on, with Mr. Kesinger's perusal of all of these factors. Mr. Brown has been in on it, too. I really believe there is nothing to qualify in the future costs that we have reflected in this estimate.

Now, there are many items of contingencies which have been eliminated in this sifting process which to my mind are justified in the actual estimate which we have prepared. I think in my own mind that many of these things which we have called contingencies are so probable that personally I would put them back in there. Walt Davidson has testified that he has a large number of cracked cylinders on his compressors. They are operating satisfactorily at this time, but we cannot tell when they are going to break. He has indicated that he is going to try to weld these cylinders. He has estimated that he is going to be successful in replacing half of them. I believe that is a speculation. This six-ton casting that we have got there is an intricate thing that is difficuult to weld under any circumstance. There is no doubt in my mind that we are not going to be able to successfully weld half of these cylinders, and I believe that in an estimate of this character it is within the realm of probability to call for the complete replacement of these cylinders. Walt, however, has included the replacement of just one-half of these cylinders. I think that in providing for the replacement of half the present number of cylinders and for the welding and saving of the other half we have been too conservative, because the probability is that we will have to replace them all. It will cost more to replace them all than it would to weld half of them and replace the other half. The replacement of those cylinders is a major item of expense, which we have not included in our estimate at all.

I will tell you another instance where I personally think there is some reason to doubt the low cost that we have reflected here. We have initiated a program of installing booster stations. I believe the lay-out has been described

to you in sufficient detail. There was no such booster unit available when I had this idea of putting individual boosters on wells. The Cities Service Company had put a booster at a central point where they collected the gas from a large number of wells. Now, such a station as that will require attendant labor; it will require the maintenance of heavy equipment; it will require large horse power, because the intake of that station is dictated entirely by the delivery requirements of the lowest pressure well in that particular group. Now, contrast that with this idea that we are advancing here. We have developed
this unit through the cooperation of the Cooper Com-
769 pany and have installed one of these boosters that has
been running now since last October. We contemplate that these boosters which will be installed, with such safety devices as are capable of protecting the machine within a reasonable degree, will operate without attendant labor. It will not be necessary to develop any water supply for the station; the housing problem is eliminated; but there is a big speculation on whether that unit is going to work out successfully or not without this attendance. When we get ten of these units all strung out on a line and depend on automatic devices to shut them down if anything goes wrong, whether they will run continuously without attendant labor is something to speculate with. Now, if we find out that we have to go to such a station as the Cities Service Company have installed in that field, it will require at least twice the investment that we have allowed for these booster stations and twice the horsepower.

I could go on indefinitely, within reason, with any number of these contingencies that I believe should be contemplated in this budget, and for these reasons I believe that this cost that we have reflected, both in operation and in future capital cost, is the minimum. Now, there is one thing to bear in mind. When you compare this system with any other that is operating in the country, to my mind there is no degree of comparability at all. We have got something more than a hole in the ground from Texas to Chicago here. We have a line that is operating at high pressures. High pressures in themselves do not mean anything, if you have the steel to hold them. The reflection of the high pressure is only what may happen in the event of a rupture. The merit of this pipeline system, however, the very economy and the very reason which justified it is the fact that we work this steel at stresses far beyond those on any pipeline that is in existence. When you are working this steel as we are, you just cannot take a chance on having anything happen.

Now, this factor of reliability is, I think, reflected in the load factors that we have carried. We could not have convinced these industries along our line and in Chicago that it was worth while hooking up to this natural gas supply, unless we had demonstrated that this reliability means something to them. The only way that we can get this reliability into the system is to keep forever after the trouble that we may anticipate, so there is a continual round of inspection, inspection of this and of that, just to establish that it is all right. The compressor station equipment is overhauled completely every year. I think I can say this, that I know it as a definite fact that there is no natural gas company in the country that goes to the extent that we do to insure the reliability of this service in the degree of overhauling compression equipment. The boys in the field right now are active on all of their erosion control on this pipeline, anticipating what may happen with snow, ice and what not this winter. The summary is that we are not taking any chances at all with any part of this equipment that we have. Our instructions are to keep it up to the highest degree of safety, not only for this reliability that I have indicated, but also for the safety of the personnel that operates it. In other words, eternal vigilance is the price of safety, if I may make a pun on a famous expression. (Motion by Commission Counsel to strike so much of witness' last answer that goes to any period beyond the immediate future denied.)

770 STANLEY GILL, recalled by defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 3, 1939.)

I have already stated my qualifications at the time I testified before. My first work in the Panhandle field was in connection with oil operations. I was employed by the Gulf Production Company; and from sometime in 1927 on I was more or less actively engaged in work in connection with oil operations, principally corrosion studies related to the sulphur water produced in the oil areas and also certain evaporation studies and studies of corrosion or gathering lines; and studies on gas lift operation, which was apart from corrosion. We were not much interested in gas. I was generally familiar at that time with the gas, but the gas did not amount to much in the beginning. The operation of the gas field was not of particular interest to the Gulf organization. That work continued until the end of 1931, at which time I started my consulting practice.

Since 1931 I have been engaged a considerable part of the time with some job or other relating to gas in the Panhandle, and have been in and out of the field intermittently over the period of years since January, 1932. My work since 1932 in the Panhandle has been concerned entirely with the gas operations, both in the sweet and sour gas areas. I am familiar with the producing conditions, existing pressure conditions, and the various problems that are incident to the drilling and operation of gas wells and the gathering of gas in the field.

You ask what part I had in making the engineering studies which have been brought into this proceeding through witnesses, namely, Mr. Kesinger, Mr. Bussard, Mr. Dickinson, Mr. Powers, Messrs. Davidson, Mr. Strong, Mr. Bulla, and others. My primary contact has been with the problems related to the study of field operations; that is, up to the time the gas goes into the compressors at Fritch. I have not had any particular contact with the detail of the estimates from that point on. My first contact with this particular job was, I believe, in January or February, 1938, at which time I was employed by Mr. Kesinger to advise with him and with Mr. Bussard and with Mr. Kuhne on the method to be employed in making forecasts of production development programs. Mr. Kuhne is a production engineer for Texoma Natural Gas Company at Amarillo. I don't remember the exact sequence of the thing. I think my first conference on that was in Chicago. I made two or three trips to Chicago, and several trips to Amarillo in this connection. Mr. Kuhne had made a more or less rough preliminary estimate, based on a study of back pressure curves, for Texoma wells; and employing an arithmetical averaging method for predicting future performance. I reviewed that work with him and with Mr.

Dickinson, and took the Texoma back pressure test data and used that and the Railroad Commission's rock pressure and open flow figures, over a period of two or three months, and developed a method based on weighted averages which I applied to the same problem. I developed a lot of calculations and certain generalized conclusions. I conferred with Mr. Kesinger, Mr. Bussard, and Mr. Dickinson on those methods, and sent numerous curves, calculated in various ways, to both Amarillo and Chicago; and sat in on conferences in Chicago and in Amarillo, in which the basis of the methods used by Mr. Bussard was discussed and decided on.

771 I am familiar with these back pressure curves that were presented here by Mr. Bussard in his Exhibits 89, 90 and 91, which were used in connection with his testimony. No. 91 is the back pressure extrapolation, and No. 90 is the map.

The application to wells of back pressure tests and the computing of curves from data contained in these back pressure tests are relatively new things. They have been applied ten years or so. There is nothing new however about the principle. The principle on which the Bureau of Mines based the development of their tests is, of course, the same principle of computation of gas flows and pressure drops as has been used for a long time; and it is the principle of our formulae, such as the Weymouth formula, for the computation of flow of gas in pipes. The basic principle there is that the rate of flow of gas is a function of the difference between the square of the absolute inlet pressure and the square of the absolute exhaust pressure.

The Bureau of Mines' engineers recognized the need for a test method which would give the information that the industry needed from these test results; and working from the principle that the rate of flow would be the function of the difference in the squares of the absolute pressures, made a rather exhaustive series of well tests. They developed methods for computing the pressure at the sand face; and found by a study of their test results that in general the rate of flow of gas was a direct mathematical function of the difference between the square of the absolute formation pressure and the square of the pressure which existed at the bottom of the well against the sand face while the well was producing.

Having confirmed their hypothesis, that it would be a function of that difference in squares, they then presented their method; and all that these back pressure curves are, this straight line on logarithmic paper, is simply a graphical method of expressing that one thing, that the rate of flow is a function of the difference between the square of the formation pressure and the square of the pressure within the well at the face of the sand. Mathematically the formula is that the rate of gas flow is equal to a constant times the difference between some pressures raised to some power, which is "n". That is equivalent in saying in lay terms that there is a constant or definite relation between open flow of the well and the pressure for a given set of formation conditions.

Questions by the Examiner.

This is in substance exactly what is set forth in Monograph No. 7. I am not sure that it is all set forth in Monograph 7, or whether it is more fully covered in the early reports of the investigation; that is, in Reports 2929 and 2930. But what they did was to develop methods of calculation of pressure at the sand face, which were essential. They then studied their experimental data, working from the hypothesis that the rate of flow would turn out to be an explanation of the function of the difference in squares of the pressures, and found that it was true. The formula, of course is $Q = C (P_f^2 - P_s^2)^n$. That, of course, is the type of relationship which is expressed by a straight line on log-log plotting paper.
772 The industry needed a test which would give this additional information; and the Bureau of Mines provided a formula and method which gives the information that the industry needed. I do not remember whether the introductory paragraphs of either report 2929 or report 2930 or Monograph 7 indicate the object or purpose of the Bureau of Mines in making those reports. Those publications do point out uses which can be made of the method and the data which can be derived from those test results, which were not available under previous methods of testing. By what I have said I intended to state that this work of the Bureau of Mines supplied a need in the gas industry.

Direct Examination by Mr. Morgan Resumed.

There was a very definite need for a type of information which could not be secured by the then existing tests. This back pressure test method accomplishes essentially two things that were not accomplished prior to its introduction. The first is to give a substitute for the old method of determining the potential by measurement with the well flowing wide open. That has been referred to as the Pitot Tube method. The Pitot Tube method was a method of measuring gas flowing out of the well while it was flowing wide open. This method was wasteful and dangerous. It was recognized as a poor method for those reasons. The industry did not care so much about it being wasteful particularly, but they did not like it on account of the danger in it.

From the waste point of view, there are two common methods of running these back pressure tests. One is by the use of what is called the various critical flow pressures or orifice tester, which is a device which is described in Monograph 7. It is a small orifice which is put on the head of the well, and through which the well is allowed to produce against atmospheric pressure. By that means a certain amount of gas is wasted, but it is a small amount, since the production has to be taken through a small orifice. The test can be qually well conducted, and is very frequently conducted by using meters which are regularly installed on the wells, and by producing gas during the test period into the line. In that case the waste is entirely eliminated.

From the standpoint of dangers, the hazard of running potential tests is practically eliminated. In running open flow tests there is a fire hazard, because we have a well flowing a lot of gas into the open air; and my own thought is that the greatest hazard is the hazard of tearing out the bottom of the well, because I had a lot of work in a country where you can't flow wells wide open. They have loose sands, which will simply tear the bottom hole fittings all to pieces, and you simply cannot do it by using the open flow on those wells. In fact, the deterioration of open flow potentials was impossible prior to the development of this method.

The use of this back pressure method of making these tests results in additional information besides that dis-

closed by the Pitot Tube test. It does two things. The second to my mind is the most important. These back pressure test curves are frequently referred to as delivery capacity curves, rather than as back pressure test curves. That nomenclature, delivery capacity curves, indicates what is probably their greatest value as operating information. The curves can be applied, not only as they have been applied here, for the prediction of potentials at any future time when pressure has declined to an assumed value; but they also show directly how much gas a well in the condition in which it was at the time the test was made will deliver against any specified
773 back pressure. That is, we can take a gas well, and from the delivery capacity curve or back pressure test curve, we can see how much gas that well is capable of delivering into a line at 200 or 250 or 300 pounds line pressure. Now, that could not be determined at all from open flow tests; and that is the type of information which is invaluable in the operation of gas properties, which could not be obtained previously, prior to the development of this test method. I think the greatest use of the information that is gained from such tests is in determining the present flowing capacities of wells at any given or assumed back pressure. For example, if a well is being produced into a line, the working pressure of which is 200 pounds, you can take the back pressure curves, or the back pressure test information, rather, and determine how much gas that well will put into that line against that working pressure. That is the information that is of greatest value in its practical application.

I have examined the procedure which Mr. Bussard adopted in dividing the areas in which Texoma has wells and properties yet to be developed into groups—I believe thirteen groups—as reflected on Exhibit No. 90 now on the board before me. In the method of calculation and prediction that Mr. Bussard employed, that division into groups was really essential to the planning of the development, gathering and boosting program. The boosting program particularly could not have been developed on the basis of county averages, or anything of that sort. What he did was to divide the Texoma holdings into groups of wells in which the performance of the wells in a given group was comparable, and in which the geographic location of the wells in the group was such as to enable him to plan the future program. There were advantages in using these groups as opposed to counties, from the standpoint of producing conditions because the wells in any group will have rather comparable performance. In other words, the probability is that a well drilled in any one of those group locations will conform in its performance more closely to the average performance of the wells in that particular limited area than it would do to the average of the performance of the wells spread over the entire field or over a county. In any group the pressures are comparatively uniform throughout. In any county that you could name in this field you will find pressures approximating original pressures and pressures that are very low. You will also find productive areas and areas of comparatively small productivity. This is reflected by Mr. Hughes' maps which were put in earlier here. We would also find the conditions as to inside and outside drainage from Texoma's leases entirely different and wide variations if you took it by counties. Some of these difficulties have been overcome by the breaking of this area in which Texoma owns producing properties and properties to be developed into groups as Bussard has done. I am in accord with the conclusion reached by Mr. Bussard that the average of the back pressure curves of wells to be drilled in those areas, together with the wells that have already been drilled in those areas, will approximate the average back pressure curves that he computed and that he shows on his Exhibit No. 89. I think that is the only sound and reasonable conclusion. I think Mr. Bussard has made an entirely sound and scientific application of good engineering principles in determining the potential producing capacity of wells to be drilled in the future at the pressures which would prevail at the time those wells were drilled. I agree with his methods.

774 The estimates of the future producing capacity of wells as indicated by these back pressure curves and as calculated by back pressure tests which form the basis of those curves is based on the assumption that the producing characteristics of the wells will remain unchanged over future years. Now, as a practical operating proposition in the field, they won't, and the productivity of the wells in the future as a practical matter will be lower than the productivity that is predicted by this strictly scientific method.

I think the method employed by Mr. Bussard in computing the number of wells that will be required to meet the market outlets of Texoma on a basis of back pressure curves as he has stated he used those curves in those computations is scientifically correct; but I do not think that the number of wells that that scientific calculation calls for will, down the years, produce as much gas as those calculations say they will. We know as a matter of fact that the back pressure curve of a given well does not stay the same over a period of years, that due to effects which act to reduce the effective permeability of the formation surrounding the well bore the back pressure curves tend to shift to the left. In other words, the productivity some years from now will be less for a given pressure difference than would be predicted from a test made today. Now, the effects that serve to bring that about are, in general, effects which reduce the permeability of the formation immediately surrounding the well bore. Those effects are, so far as we know, occasioned principally by two things: One of them is simply the effect of the velocity of the gas moving into the hole, and the second more important class of effects is that related to water, both salt water from the bottom or from above, and fresh water, which is condensed out of the gas as the pressure is reduced in the movement of the gas into the well bore.

Salt water will produce various effects, of which one is the clogging of the capillary pores by liquid water. Some of the pore space, through which this gas can move, is shut off unless room is left for it to come around. Or salt water from above trickling down over the face of the well bore is evaporated by the gas leaving a deposit of solids—that is, salting up,—which also clogs the formation. Water in the formation, and particularly fresh water which is contained in the gas and which tends to condense out of the gas as pressure and temperature are reduced, causes the formations, and more particularly shale, to flake and powder, and this broken formation, if it is dropped out back from the well bore clogs the pores and reduces the permeability of the formations.

Shale and other formation matter from up the hole also falls back down into the hole, either dislodged by the gas stream or loosened by water condensing out of the gas stream, falling down to the bottom of the hole, and has to be cleaned out periodically by blowing or other methods. But some part of that over a long period of time apparently stays stuck to the walls of the hole and clogs the pores still more.

Salt water which comes in laterally through the producing formations will take up a certain amount of pore space, just fill up a certain number of pores through which gas is moving now, and just won't give gas a chance to get into them.

775 Salting up is more a matter of salt water trickling down from above and leaving a deposit of solid salt on the face of the well bore. This formation of salt operates to reduce the productivity of the well or the producing capacity of the well by closing up or reducing the pores or channnels through which the gas flows.

As a practical matter, there is no way to counteract those influences that happen in the producing formation. We know that the productivity of wells decreases with time. All of those factors act to decrease the productivity. Now, theoretically there might be a change where some of the formation on the walls of the hole down at the bottom might come loose and fall in and open up a little bit more pore space, but as a practical matter, as far as I know, if it does happen at all it is over-balanced by these other things, because the actual effect is the reduction of productivity with time. I know of no data on the basis of which such correction can be made through which we can ascertain how much this interruption or interference with the predicted open flow indicated by scientific calculation in conjunction with the application of the back pressure test principle. I think the proper scientific procedure is to take conditions as they exist today and calculate your prediction on the basis of those conditions. If the data were available, correction could be made, but there is no way to be sure of just how much that shift will amount to.

Mr. Bussard recognizes that it is going to take more wells than his study indicates to supply the quantity of gas which will be required by these pipelines. It is no criticism of Mr. Bussard to observe that more wells will be required and that it is going to cost more to get that gas than Mr. Bussard's figures indicate. The drilling of additional wells would increase costs all up and down the line. There would have to be additional meter settings, more gathering lines, more men to operate those gathering systems, to change charts on those meters, more people to calculate the charts. Then it will also require more booster horsepower, not because of any changed total quantity of

gas, because the quantity of gas would be the same, but because these wells at the reduced delivery capacity will have to be opened up wider to produce the same quantity of gas That will mean lower working pressure and, consequently, greater booster horsepower in order to ram the gas into the main gathering line. I have heard Mr. Dickinson's testimony concerning what he termed the orderly distribution of this drilling over the years instead of waiting until it was a physical necessity to have the production. He assigned two major reasons why that was done. One was to minimize the cost and to keep the supervision of this drilling under the eye of the trained personnel, which could not be accomplished if the wells were all drilled, or a comparatively large number of them were drilled, over a short period of time. The other reason he assigned was that from an engineering standpoint it was desirable to postpone as long as possible the production of these wells up to the limit of twenty-five per cent allowed under the Texas statute. I think Mr. Dickinson is entirely correct in this last observation. As a matter of general practice, it is bad to operate a gas well at too high a percentage of its open flow. Twenty-five per cent is the established statutory limit in Texas, as in many other gas producing states. That is an absolute limit, and is a much higher percentage of open flow than is best for good well performance. All of
776 the troubles that occur in gas well operation are accentuated as you operate at progressively greater percentages of the open flow rate. You just have a great deal more difficulty and expense in keeping the wells in good operating condition.

Referring to Mr. Dickinson's testimony that Texoma has operated its wells at a rate of less than ten per cent of open flow throughout the history of that company, in my judgment, it is a very good practice. It reduces the amount of work that is necessary to keep the wells operating and the cost of keeping the wells in operation. It operates to postpone the time when these complications about which I have testified as occurring in the bottom of the wells will overtake the operator. Take, for example, the problems that result from condensation of water out of the gas in the hole. When a well is operated at a lesser percentage of its open flow the drop in pressure and temperature as the gas moves into the hole is much less than when it is operated at high percentages and, therefore, there is much less condensation of moisture in the hole. The same is true of velocity. Essentially the velocity of the gas through the formation is a function of the percentage of open flow, because maybe one well will have an open flow of fifty million and another well will have an open flow of ten million. The velocity in the formation is not five times as much on the fifty million well as it is on the ten million well. It is pretty much the same. That difference of potential means principally that the fifty million well just has about five times as much open passage for delivering gas to the hole. That difference then between those two wells does not make any difference practically in the formation velocity, but if you operate either of those wells at twenty per cent of its own open flow capacity, you will have about twice as high a formation velocity as if you operate that same well at about ten per cent of its own open flow, and that increaseed velocity has an increased tendency, of course, to break down the formation.

I am familiar with the charts contained in Exhibit No. 91. I have gone over and examined the method employed by Mr. Bussard of extrapolating the course of the weighted average pressure curves of the respective groups set forth on Exhibit No. 90 and continued over to Exhibit No. 91. I think that is a reasonable basis of extrapolation of the possible method of predicting the future course of rock pressures in these groups. It is the method which, first, seems to be most in accord with the performance of the wells up to the present time and, second, it is the method which leads to an indication of the best future well performance; that is, it is the basis of extrapolation that indicates Texoma will require the least number of wells in the future. By that I mean this: On these pressure curves you have certain fixed data. First take this Figure 8 that is curved for group 8 on Exhibit 91. You have the data on past performance of the weighted average rock pressures of the wells in the group. That runs from 1935 to 1938. That gives you as basic data the course of the actual decline of rock pressures for a period of years. The other fixed point is fixed by the basic estimates of reserves. Mr. Peterson's estimates ha been used by Mr. Bussard in preparing those curves, and the predicated rate of withdrawals from the field as a whole is from the estimate which I believe Mr. Dickinson presented here. He did a great deal of work in connection with it. That gives you then another datum of pressure and time at the end of this extrapolation, so that the extrapolation consists of 777 getting from the 1938 point to the terminal point, which is 1954, with twenty-five pounds per square inch gauge pressure at the wellhead.

Now, there are three ways the extrapolation could run. It could run from this 1935 to 1938 curve, running convex upwards, or the 1938 point could be connected to the 1954 point by a straight line, or the extrapolation could be made concave upward. It is apparent from both of these groups, both Group 1 and Group 8, that the extrapolation in the form that has been made, convex upwards, runs along reasonably in accord with the course that the pressures have taken so far. From point of view that looks like the most reasonable means of connecting these fixed points. This form of extrapolation of a curve convex upwards, which of course means that the pressures will fall off at a lower rate in the beginning than they do towards the end, is also in accord with reasonable expectation of what will happen in the Panhandle field as a follow-up to what has happened. That is, as has been mentioned before, the heavy withdrawals up to the present time have been from those parts of the field in which the reserves were greatest. Now, later on in the life of the field there will be more and more development and withdrawal out in areas which are now the higher pressure areas and those withdrawals from those higher pressure areas will bring about an accelerated decline in average pressures.

We have already gone pretty thoroughly into the reason for this. It is a matter of the size of the container in relation to the withdrawal. The circumstances that many of the high pressure areas are of low productivity, or what is called lean areas, will involve the future behavior of pressures. Withdrawals of the kind that have occurred could not have taken place if the reserves had been equal. I mean, if you step out into the higher pressure areas and move your withdrawals into the higher pressure areas you will get a higher average decline. Looking at the picture from the standpoint of potentials or the producing capacity of Texoma's wells in the future and taking the course of that curve as interpreted by Mr. Bussard, and comparing that course with a straight line or a line which has a concave curve upward, either a straight line or, to a greater extent, a curve concave upward would indicate that the pressure at any point between the 1938 pressures and the terminal pressures, which are the same for each of the three, would be lower than the pressures which are indicated in the form of extrapolation used. At any point of time between 1938 and 1954 on the other forms of extra-polation would indicate a lower pressure. Take, for example, this Group 8, and say for 1945 the form of extrapolation used indicates a pressure of slightly over 300 pounds per square inch, a straight line would indicate a pressure below 250 pounds. Now, taking those two lines for the time being, the curve used by Bussard, which indicates an average pressure for group of 300 pounds per square inch, would indicate a higher producing capacity for Texoma's wells as of 1945 than would a straight line which indicates a pressure of less than 250 pounds per square inch. This is due to the circumstance, of course, that the relation between the potential and the pressure remains constant, using those average composite curves. And since the pressure is lower, following it down the straight line, the potentiality or producing aggregate of Texoma's wells at any given time will follow that pressure down in the same relationship and will indicate a lower available potential for Texoma.

778 Applying that principle to the drilling program of Texoma, the use of a straight line extrapolation would call for a considerably heavier drilling program than does the use of the extrapolation which was employed. The conception or interpretation of Mr. Bussard of the course of that line operates to convince him that there will be a fewer number of wells required than would be the case if that line went down on a straight line from its position on January 1, 1939, to its position at the end of 1954. (Motion by Commission Counsel to strike the testimony of Mr. Bussard with respect to results which would have been achieved or might be expected through the use of other line projections denied.)

If the decline of pressures was strictly proportional to withdrawals, in other words, in any field to which the pressure decline method can be properly applied for the estimation of reserves, a straight line extrapolation would be proper. That is, where there is the condition of equal withdrawals ratably over the field to reserves in place, so the pressure decline is uniform all over the field, and where the condition of every acre in the field is such that it originally had the same reserve as every other acre, then a straight line extrapolation and a straight line decline of pressures are experienced. That is not the situation in the Panhandle, and I do not believe that this curve will take the course of a straight line from where it is found on January 1, 1939, to the point which it will reach at the end of 1954.

Questions by the Examiner.

The charts in Exhibit 91 represent a function of Boyle's law, as modified by the sub-surface conditions. What I have just pointed out are conditions that would affect the operation of Boyle's law one way or the other. Under the strict application of Boyle's law, these declines would have a straight line relationship.

Direct Examination by Mr. Morgan (Resumed).

I am familiar with the terms "liners", "tubing" and "clean-out tools", mentioned by Mr. Dickinson in his testimony, in which connection he stated that it will be necessary to install liners on some of Texoma's wells, that in other wells and in perhaps some of the same wells it will be necessary to install tubing and that it will be necessary for the company to equip itself with clean-out tools and equipment going with clean-out tools, for the purpose of keeping those wells in reasonably good producing condition. Basically, the function of a liner in a gas well is to let the gas through and hold the formation back to keep cavings from coming into the hole. Looking over Mr. Dickinson's estimates I got the general impression that he probably did not provide for enough liners. I think the need for liners is going to be the rule rather than the exception, especially in the set up of Texoma's wells. Most of the wells will require liners, especially later on in their life when the pressure gets down to the point where you cannot blow them clean so well and when water conditions in the formation are causing more and more cavings.

The use of tubing is to facilitate the operation of blowing the wells clean of water, cavings and scale which fall into the well bore. By the use of tubing you are able to clean the wells by blowing more readily, and thus avoid cleanout jobs with tools. It is not particularly necessary in the early life of a gas field or a gas well to use tubing,

because the well produces a large enough quantity of
779 gas so that when you open it up through the big pipe
you get a velocity of gas flow sufficient to carry this foreign matter out of the hole. Later, as the wells decline in productivity, the volume of gas produced when the wells are opened up is not sufficient to give a velocity sufficient to carry the heavier materials out of the hole. By installing tubing and by blowing through a small tube string, instead of through large casing, the velocity of flow with the same volume of gas being produced is greatly increased; that is, approximately, comparing an 8-inch casing with a 2-inch tubing, the velocity for the same total volume of gas will be sixteen times as great in the two-inch tube, so it will carry out this stuff when it will not carry it by flowing through the 8-inch casing. Thus, by putting in tubing when it gets so that you can't blow the well satisfactorily by blowing through casing, you are able to clean in later life and thus reduce the number of clean-out jobs with tools which are necessary.

Mr. Dickinson testified that in his judgment it would be necessary to install tubing in two hundred and four wells out of the total of three hundred and fifty wells. If I were guessing at it, from what I know of the field, I would guess three hundred and fifty. I think it probably will be necessary to install tubes in all of them. I think that is somewhat of a guess. I think Mr. Dickinson probably made his estimate based on a detailed study on each individual well. I base this on what I might term a broad gauge estimate, though it is not one of those boiler house estimates that Mr. Dickinson was talking about. I have been guilty of boiler house estimates, as everybody else has around the oil field, but this is not a boiler house estimate. It is probable more wells will have to be tubed than Mr. Dickinson has estimated.

As to clean-out tools in the declining years of a gas field, I have never yet seen a gas field where you did not need them. They are essential. Mr. Dickinson has provided for two strings of clean-out tools and the essential equipment for use in the clean-out operations on Texoma's wells, numbering one hundred and thirty-five on January 1, 1939, plus those which have been added since January 1, 1939, and the wells to be drilled, at the rate of approximately twenty a year for the next several years. I think Mr. Dickinson is pretty optimistic. I don't think that one string of clean-out tools will take care of one hundred and thirty-five wells. In general, I would say under conditions such as those in the Panhandle that barring accidents that will occur on an occasional job, it would keep one clean-out rig humping to keep up with a hundred wells. It is doubtful if one clean-out rig can keep up with more than seventy-five or eighty wells satisfactorily. That would call for four or five strings of tools.

Speaking of the personnel employed by these pipelines and the policy of the companies in furnishing housing facilities for their regular employees, I am familiar with that policy and have seen some of their camps. I have heard of their other camps but have not seen the compressor camps up the line. I have visited the camps at Fritch, Kingsmill and I seem to have a recollection of having seen their camp at Dumas. In the latter camp there are only one or two houses. It has been my experience and observation that it is not an unusual procedure on the part of pipelines to furnish their field personnel with housing facilities. It is practically the universal practice in all field activities of oil and gas companies everywhere. I do not mean in the Panhandle only but you will find this practice wherever there are oil or gas fields. It is the usual thing among pipelines,
780 gasoline plants, or field refinery operations. I don't
know just where this policy or practice started. There are a number of reasons for it. For one reason, you just can't keep the men you want unless you have those facilities. It is such a thoroughly recognized custom in the field that men want to live on the job. That is fine from the standpoint of the employer, because it is highly desirable, and in the case of some operations, absolutely essential to have the key men housed close to the job. That is necessary and desirable principally for the emergency phase. There should be men who know the job, and who are capable of handling an emergency, on the job almost instantly in case anything should come up. It also makes the day by day operation that much easier. The men are closer to work. They get there on time, regardless of weather or road conditions. Road conditions are more often than not awfully tough around these operations. In the Panhandle it is pretty bad. The roads are bad and there is a lot of bad weather. I have gone out in the morning in the middle of a big sand storm, and come back in the afternoon through mud, heavy rain, and sleet freezing when it hit my windshield, sliding all over the road. That

is an area of high altitude and is subject to very severe weather conditions. Extreme and very sudden changes in weather occur. Also, in the Panhandle field as a whole, there are very few spots where a high class man would care to raise a family at all—in the towns outside of the company camps. To illustrate that, take the town of Borger. This town grew up thirty or thirty-five miles from a railroad to a town of thirty or thirty-five thousand people, in the middle of a big oil boom. It was a boom town of the worst sort. Every place that you ever heard of was rampant in the town, and I think still is. It is a dump I should say. It is a very undesirable place. There are no decent residences. There are shacks, and a few fairly nice business buildings, and more that are far from being decent. Here is what happens in a situation of that sort. The Phillips Petroleum Company have a big refinery which is just a mile or two from Borger, and so far as I know none of the employees of the Phillips Company live in Borger. The Phillips Company have a camp which is practically a city. It is a city, it is a separate town called Wittenberg. It is completely a Phillips town. There is a school, elaborate recreational facilities; and so far as I know none of their employees live in Borger.

781 G. M. DAVIDSON, recalled by defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 3, 1939.)

I have prepared a list in compliance with the Examiner's request that I give him a break-down of the number of automotive units by classification and by name. It should be cross-referred to page 2 for Natural Gas Pipeline Company and pages 3 and 4 for Texoma Natural Gas Company. This list of equipment includes the following: For the Natural Gas Pipeline Company there are ten International trucks with trailers; thirteen Chevrolet pick-ups; twelve Chevrolet coupes; sixteen Chevrolet sedans; and there are nine No. 22 Caterpillar tractors; and four heavy passenger cars, a total of sixty-four units. Referring to Texoma Natural Gas Company, there are three International trucks; five Chevrolet pick-ups; eleven

Chevrolet coupes; four Chevrolet sedans; one No. 22 tractor; and three heavy passenger cars, a total of twenty-seven units.

This morning in a hasty glance at page 2, pertaining to Natural Gas Pipeline Company, I failed to notice, it being rather difficult to read across these lines, that there was an additional car for the telephone department to be purchased in 1947, making two additional cars, noted on Line 25. Now, the question I think also was brought out as to why we replaced a car in 1942 and 1943. I think this can be explained by considering the car's life as being twenty months. Then if you were to buy it early in 1942 you would replace it by the end of 1943. There is the required stretch of twenty months in there. It is rather complicated to clear it up when it becomes two cars purchased at different intervals in there. It is just a matter of following our fixed policy of replacing these cars at regular intervals, rather than running them until they are ready to fall to pieces.

782 P. McDONALD BIDDISON, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 3, 1939.)

My name is P. McDonald Biddison. I live in Dallas, Texas, where I have resided since the fall of 1931. I am a consulting engineer, specializing in natural gas and petroleum work.

I graduated from Kansas State College in 1904 with the degree of Bachelor of Science in electrical engineering. After about one year of work at Iola, Kansas, as a draftsman, electrician, instrument man, and stationary engineer, and a few months at Ziegler, Illinois, as an electrician, I began to do engineering work in the natural gas industry at Columbus, Ohio, in 1905. I was employed first as a draftsman on plans for work for the Kansas Natural Gas Company under the chief engineer of the Logan Natural Gas and Fuel Company, who was the consulting engineer for the Kansas Natural Gas Company. I later succeeded him as chief engineer for the Logan Natural Gas and Fuel Company.

In 1907 I went to Joplin, Missouri, with the Hope Engineering and Supply Company, and was engaged upon designs for natural gas properties proposed to be constructed. Late in that year I moved to Independence, Kansas, as assistant to the chief engineer of the Kansas Natural Gas Company, and was engaged in supervision of construction and in the design of compressor stations and pipelines.

In the fall of 1908 I went with the Columbia Gas and Electric Company as construction engineer, and built for them a compressor station at Kenova, West Virginia, and supervised the construction of the western end of their 20-inch line into Cincinnati.

Following this I was employed for one year as construction engineer by the Ohio Fuel Supply Company in Ohio. That system is now a part of the Columbia Gas and Electric properties.

Following this I was employed for a year as construction engineer by the Texas Company at their Port Arthur works on the installation of the steam generating equipment, electrical generating equipment, and water supply for the refinery, and as consultant on the design of concrete building foundations.

In 1912 I again became associated with the Ohio Fuel Supply Company as construction engineer, and remained with them until the spring of 1919. My duties were design and construction of the gas engine driven compressor stations, measuring and regulating stations, distribution systems, pipe lines and shop buildings. While I was employed by the Ohio Fuel and Supply Company I also acted for a four-year period as consulting engineer to the Lone Star Gas Company in Texas. I designed for them and supervised the construction of compressor stations at Petrolia, Texas, a gasoline plant at Petrolia, Texas, and laid out their programs of additions to lines and station capacity. I predicted for them each year for a four
783 year period the number of wells required to be drilled
to maintain their gas supply.

During the time that I was with the Ohio Fuel and Supply Company I also conducted research upon the extraction of gasoline from natural gas in cooperation with the United States Bureau of Mines; and for a period of about three years I had supervision of gasoline production for the Ohio Fuel Oil Company in West Virginia.

During the period of the War I also acted as consulting engineer to the United States Bureau of Mines on war gases, and supervised the helium production program to the point where helium plants at Fort Worth were ready to begin operations.

In the spring of 1919 I went to Mexico and was there for two years on the construction of oil pipe lines and oil loading facilities; the first year I was with Atlantic Gulf and West Indies Steamship interests, and the next year I was with Tide-Mex Company, a subsidiary of the Tidewater Oil Company.

Returning from Mexico in 1921, I became associated with the interests who owned the Dallas Gas Company and some producing properties in north Louisiana. I acted as consulting engineer to the Dallas Gas Company and to the County Gas Company, an affiliate. I supervised the development of production and the marketing of production from the Louisiana fields. During this period I constructed some pipe lines, some distribution systems, made gas sales contracts, and reported upon pipe line projects to such markets as there were available to lines out of the Monroe field area; some of which lines were subsequently built, and one of which I started construction on, but sold the properties before construction was completed. Upon the sale of these producing properties, I remained with the properties for about one year and participated in negotiations leading to the construction of pipe lines to New Orleans, to Memphis, and to St. Louis, as an engineer for one of the parties in interest in those lines, and supervised the construction of the pipe line from New Orleans to Baton Rouge.

In the fall of 1928 I severed my connection and opened an office in Monroe, Louisiana, for the practice of consulting engineering. During that fall I reported to the financiers upon the project for a natural gas line into Salt Lake City, which was constructed, and made a valuation of the property of the Lone Star Gas Company's distribution plant at Fort Worth. Following this I became associated about the first of January, 1929 with the Southern Natural Gas Corporation, for which I acted as consulting engineer during the construction of their pipe line system extending from the Louisiana gas fields across Mississippi and Alabama into Georgia, and down past Mobile, Alabama, into Pensacola, Florida. Upon completion of their construction work and the substantial completion of their sales contract arrangements, I severed my connection and moved to Dallas, Texas, where I have been located since, engaged in consulting work. I have been very largely connected with valuations of natural gas properties and with testimony before courts and commissions with regard to values of that class of properties.

784 I have knowledge concerning the properties of Texoma Natural Gas Company and Natural Gas Pipeline Company of America. This knowledge I acquired by making two inspections of the properties of these two companies. The first inspection was made in March, 1938 and the second in May, 1939. The purpose of these inspections was to determine the condition of that property, to familiarize myself with the methods of construction used, the methods of maintenance used, the degree of care used in maintaining the property, the degree of safety maintained in the companies' operations, and the degree of safety of their installations. I have in process of preparation a study dealing with the condition of the pipe line, which is to be introduced later in connection with the reproduction valuation.

I was asked in connection with my employment to observe the personnel and to make a confidential report on the personnel to the management. I have made such report.

On both of these inspections I began at the field on the system which is the property of Texoma Natural Gas Company. I inspected down there wells, well measuring stations, pipe lines, and telephone lines, to determine their condition. The inspection of pipe lines was accomplished by having sections of pipe line exposed by digging a bell hole. A bell hole is simply a hole big enough to get down in and see and work around a joint of pipe. The bell holes which we requested to be dug on this property for that purpose provided for approximately six feet or more of length of the pipe to be exposed, of which four feet was to be cleaned of any protective coating or rust or scale. They were large enough so that the pipe was exposed for its full circumference so that the entire body of the pipe could be seen and inspected. The clearance under the pipe was sufficient that one could get down under the pipe and look up at it. The clearance on the sides was ample to permit free access to the pipe all around. Since the pipe is of varying size in the field lines, of course the holes were of varying sizes. For the first inspection the intervals at which these bell holes were opened were approximately five-mile intervals over the pipe line and over the gathering system. When I went back to inspect it a little over a year later those bell holes had been filled up, but on the second inspection they opened new bell holes to the number of about half as many as those opened on the first inspection. Taking the two inspections together, an aggregate average of about three holes was opened for each ten miles of pipe line. This obtained throughout the main line and the gathering system.

I inspected and examined the field facilities, the wellheads, the various plant equipment, as well as the personnel out in the field. I saw their automotive equipment, their tools, their clean-out equipment, and looked at their installation of stream crossings to see what their condition was and what the prospects were of their maintaining those stream beds in the status quo. I inspected the residences and warehouses at Dumas and Kingsmill. I inspected Fritch station, including the compressor station and the agsoline plant and the dehydration equipment, the residences and the warehouses there. Proceeding up over the main line I inspected pipe at locations as I have previously outlined, looked at gate boxes, and as I came up on to the property of the Natural Gas Pipeline Company of America I stopped at each compressor station and noted the condition of the various classes of equip-
785 ment in each compressor station, of the automotive equipment which was available on locations to be seen. I inspected the telephone line. I made notes as to the amount of hours of operation of engines. I examined their records of engine repairs, became acquainted with their scheme of maintenance and with the personnel in charge of operation at various stations. My inspection also included their housing facilities. I ascertained the stresses at which the pipe and the equipment on this pipe line were operated, the load factor, and other kindred features of information. I have gone over that data and made calculations from the operating pressures and the character of pipe as to what the stress in the pipe walls was and as to the degree of safety of operations.

This pipe line is not operated along the same lines as other lines from the standpoint of pressure conditions and stress conditions. It is something far in advance, from the standpoint of technical engineering, from the standpoint of economy, and the use of steel, of anything that has heretofore ever been constructed or even conceived.

Instead of basing the safe operating pressure or the factor of safety upon the ultimate strength of the steel, as has been the common practice in the design of pipe lines and of pressure vessels in general, this pipe line has had its operating pressure fixed by a ratio of operating stress in the pipe walls to the yield point of the metal, and in selecting the materials to be used the engineers who built this pipe line secured production on a large scale of steel for pipe line purposes having a relatively high yield point compared to steels previously used for such purposes. The net result was that they secured pipe which could be used for pressures very much higher than ordinarily had been used previously on pipe of this size and of the wall thickness used. The result is that they have secured a capacity per pound of steel far above anything previously obtained.

The use of these higher pressures and the use of higher stresses in the pipe walls means that on this pipe line failures must be foreseen and avoided by taking precautions in advance of their failure, otherwise serious interruptions to service will occur, and otherwise the employees and the public in the areas traversed by the lines will be subjected to risk of loss of property and of life. There is a difference in the result of the parting of a pipe line or the explosion of a compressor or of some equipment through which gas passes at the high pressures used by these pipe lines, and the result of such occurrences in the case of a pipe line utilizing pressures up to three or four hundred pounds. With the pressures at which this line is operated, the pressure being something like twice that commonly used on pipe line transmissions, the damage that would be done would be twice as much as ordinarily, by virtue of the difference in pressure.

Now, this is a large line, a 24-inch pipe line, and upon rupture the amount of energy which would be suddenly released from a line of this size and at the pressures existing would be in the order of five or six times more than that on a 16-inch line at 350 to 375 pounds. So the amount of damage that could be done by a rupture on this line would be many times that which you would expect from the usual sized pipe line at the usual pressures.

786 I have seen a number of pipe line ruptures. A pipe line rupturing at high pressures will generally throw a joint or two joints of pipe out of the ditch and will hurl it a hundred yards or more, and the escaping gas will scour out in a few minutes a hole that you can set a big truck down in. A line rupture on these properties would scour out a hole that you could get a good sized dwelling in. If a fire does not occur the area damaged would ordinarily not be so great, but the chances for fire and explosion on one of these line ruptures are generally quite high, because sparks generated by pebbles hitting upon steel may set off an explosion, under which conditions a very large area may be damaged and structures somewhat adjacent to the right of way may be damaged or destroyed. If a fire of that sort occurred at a compressor station with these high pressures, there might be an extremely high loss of property, accompanied by serious injuries and loss of life.

I have conferred with most of the men who have testified in the last few days in regard to the probable capital and maintenance requirements of these pipe lines and their operating expense over the next ten or twelve or fifteen years. I refer to the studies conducted directly under the leadership of Mr. Bussard, concerning which I have heard other witnesses testify. I have conferred with them while they were preparing the data and studied the data as they were preparing it. I am familiar with the exhibits which they have prepared and which have been introduced in evidence in connection with their testimony, particularly the exhibits of Mr. Powers, Mr. Davidson and Mr. Strong.

In my trips over the properties of Texoma Natural Gas Company I saw a stream called the Big Blue in Moore County, Texas at several points. The reason I happened to see it at more than one point is that Texoma has pipe lines crossing this stream at I think three points, and I crossed it at other points besides those locations where the pipe line crossed it. I have heard the testimony of Mr. Strong concerning the item shown on page 3 of Exhibit 105 which refers to a bridge across the Big Blue River to be erected in or prior to 1942, at a cost of $54,508.

The bed of that stream has shifting sand bars and the banks are eroding away, and changes in the banks could be detected between the inspection I made in the spring of 1939 and the one I made in the spring of 1938. I think a suspension bridge is the only way in which they can secure a permanent installation across that stream any place near the point to which Mr. Strong testifies that a suspension bridge will be erected. The revetment work and bank protection work which Texoma has done and is doing, while it retards erosion of the bank and retards the shifting of sand bars, does not and cannot prevent it. I think this improvement should be made at an early date because Texoma is dependent upon the use of the line which crosses that stream at that point for a large portion of its gas supply and to maintain continuous service that line must be kept in continuous operation. It is my judgment that about one more flood on Big Blue Creek down there will see that bridge go in in a hurry.

The next item on that page is "Two 12-Inch Lines Across the Canadian River." That stream, like practically 787 all streams in that general area, has a wide bed, with shifting sand bars and a channel which may be at one bank for a while and after a flood shift to the opposite bank. These shifts cause the movement of acres, hundreds of acres of sand in those river beds. Since a large portion of the gas supply of Texoma Natural Gas Company must cross the Canadian River through this line, it is essential, for the continuity of service, that they have lines installed across this stream bed in sufficient amount that if, upon some of those shifts of the sand bed, lines are washed out, they will have enough remaining lines to maintain operations close to full schedule. In my judgment it is a necessary engineering step to provide additional pipe line capacity at the Canadian River crossing. The only question in my mind is whether they have provided all that they would be justified in providing. They could quite readily justify providing more lines. That stream is notable for its treachery and has been as far back as the history of that territory runs. It is almost impossible to enumerate the railroad bridges, the pipeline crossings and the ordinary highway bridges that have gone down that stream. Under dry conditions it is possible to walk across that stream. Under flood conditions it just takes everything in front of it.

Another item shown on page 5 is the replacement of river headers. I am familiar with the river headers up and down this pipe line. My judgment is that these headers should be replaced. These headers were of good design at the time they were built. They were probably the best design that could have been obtained at that time. Since then, other methods of construction have become available, which enable now a design which will avoid some of the weaknesses of these headers, and it is just good judgment and good engineering to eliminate the chance for fracture in these old headers of the gusset type construction and replace them with something which is amply safe for the working conditions to which they are subjected.

The same situation and observation applies to drips. There have been improvements in the design of drips presenting an exactly parallel case to that of the headers. The headers are subjected to the greater stress, but the drips are subjected to more action from corrosion because they collect moisture.

Another important item included in Mr. Strong's program for improvements is the installing of welding sleeves at stream and gully crossings to give rigidity to the line at those crossings. These welding sleeves are not installed in lieu of the existing couplings, but are a reinforcement to the couplings. When the sleeves have been installed over the couplings, the couplings no longer have any function to perform. They can be installed in this fashion without shutting down the line. This procedure adds strength and safety to the pipe line at the coupling and is a cheap form of insurance against difficulty at those minor stream and gully crossings. These sleeves are a little thicker than the pipe and are composed of the same type of metal.

On the same page there is another item on line 6 for the laying of six new pipe lines at the Canadian River. That is the same river but not the same crossing about which I testified a little while ago. The crossing referred to on page 5 of the exhibit is the crossing of the 24-inch main line leading from Fritch up to Station No. 2. The same conditions exist at this point on the Canadian River crossing as exist on the 24-inch line leading to Moore County and there are additional reasons for providing
788 stability at this point over those pertaining to the 24-inch Moore County line, in that this line carries all

the gas which leaves Fritch station for the Chicago area. It is on the main line and if that crossing is out the whole system is out.

Passing to page 8, I note an item of 15,600 feet of 12-inch line at the Arkansas River, at a time not later than 1943. I saw this crossing upon both inspections. The river at this point has a wide flange, subject to overflow, and the river crossing there should be extended back safely out of the overflow territory. The banks on this stream, at the location of the crossing, are caving and it has shifting sand bars. I think this work should be done, and I think, further, that if between now and 1943 there is another bad flood on the river, the work proposed there will be done prior to the date for which it has been estimated.

On the same page is an item which occurs in several places in Mr. Strong's exhibit, that is, the installation of cathodic protection. That has something to do with electricity and corrosion as a result of the electricity, and is an electric method for the mitigation of corrosion. I think it highly desirable to install cathodic protection for this pipe line. There are locations along this line where the protective coating has been penetrated and where corrosion has begun. A line constructed as this line has been, with a high grade of protective coating, is the type to which cathodic protection can be economically applied. If some means be not taken to check corrosion, large percentages of pipe will become pitted, to the extent that replacement will be necessary. The installation of units for cathodic protection at the proper points along the line, where the indications are that corrosion will become severe, will very materially curtail the rate at which pipe will need to be removed and replaced in this system. It is the cheapest form of protection that can be obtained for pipelines of this character. It has not been necessary in the past to install this protection because the coating has functioned, except in the instances referred to, but there are already a few locations at which the protective coating has begun to show failure. There will be more of them.

There is also quite an item on page 8 entitled "Install Two 16-Inch Lines, Beaver River." Beaver River is in a wide valley. About three years or so ago, during a severe flood, it just simply went wild, changed its course in some locations as much as a mile, took out some stream crossings of some other pipeline companies, and is apt to do the same again. The crossing of this system's line on the south side has headers up fairly close to the south bank of the river. The river crossing lines, when I inspected them in the spring, had had some work done on them, but a new channel was working upstream toward those lines. That was in the spring of 1939. Some additional protection against interruption at this stream is necessary, and this is an economical method of achieving that result.

On page 9 of the same exhibit there is provision for installing river clamps and reinforcement straps at the Republican River.

The Republican River is in a wide valley and the stream flow at one time was confined to a narrow portion of the valley by good levees, but severe floods a few years ago took out large portions of those levees, and they have not been replaced. The result is that there are large diameter
lines in a valley that is subject to overflow, and any
789 large diameter lines that are apt to become submerged
must be stiffened up at the joints to prevent rupture
of the joints and must be weighted down to prevent their floating out. In my judgment this is a necessary precaution.

On page 10 are references to various types of replacements at river crossings, namely, Walnut Creek, Nodaway River, South River, Box Elder Creek, Squaw Creek and other creeks. I have seen most of these crossings but don't think I have seen every one of them. For the replacement work on these streams I think that it is a wise precaution to keep those wide diameter lines across these comparatively small streams well down below stream bottom. I think it is essential to do that. I think, further, that since corrosion does generally take place at the approaches to streams, it is advisable, on a line of this size, where the amount of gas that can be packed into the line to take care of interruptions is small compared with the market demands, that stream crossings should be investigated and relaid at periodic intervals to insure continuity of service. I have seen Walnut Creek, Middle Nodaway and Squaw Creek, but I am not sure whether or not I saw the others, although I am definite about those I have named. What I have said here applies to any of the streams of that character across which this pipeline runs. At periodic intervals these crossings should be reworked, and the way to re-work them, since you must maintain service, is not to repair the old, but to take the old out and lay new line.

Mr. Strong, in his Exhibit 105 and in his testimony concerning that exhibit, has made provision for future replacements of approximately six per cent of the pipe line on the main system and three per cent on the gathering system. We have no history of a pipe line with the kind of protection which has been used on this line, covering a period long enough to give any conclusive data as to the reasonableness of that estimate of pipe replacement. The estimates which have been made as to the amount of pipe to be replaced on this system are based upon the expectation that the protective coating will, in large measure, continue to afford protection in the future as it has for the eight or nine years of past life. If the company is disappointed in that, then the amount of pipe replacement which will be required will be several times this six per cent for the main transmission lines and three per cent for the gathering lines. Pipe replacement will then begin to approach that experienced by other companies, because when this protective coating is gone, then this pipe is subject to the same effects of soil conditions as would be a pipe which had been protected with something inferior to begin with, and from that time on the pitting rate will be the same as if it were bare pipe. Then, unless this coating continues to function as Mr. Strong in his study has assumed it will, my view is that his estimates are far below the actual replacements that will be required. Assuming that this coating does continue to function as Mr. Strong assumed in making up these figures, I think his estimates are reasonable. They are conservative. I think he has allowed for this purpose less than will be required, rather than more, as the future will develop. (Motion to strike above testimony denied.)

In the testimony of W. H. Davidson and in his Exhibit 97, provision is made for future investments for the renewal of red wood cooling towers in Stations 2 to 10, inclusive, and Mr. Powers testified to a similar replacement necessity in connection with the cooling towers at the Fritch
station. I am certain these installations will be required
790 Because these towers are wooden structures, bolted
together. They are high, and they are subject to shaking and to being stressed by wind and snow loads. While red wood itself is a material of long life, yet the joints in the structures become loosened and weakened, and the

method of repairing those conditions is to take them down and put up new ones. It is inevitable that they will be replaced. I think the time he has set out in this exhibit is a reasonable expectation as to the period in which that will be done. I have seen work in progress at several of the stations, repair work, and from my knowledge of structures of that sort I know that they have to be repaired and work must be done on them practically every year.

Referring to another item, shown in line 24 at page 2 of W. H. Davidson's exhibit, providing for the construction and equipping of a central machine shop for heavy machining in connection with the operations of the compressor stations, I think this item is essential. They have ten compressor stations. As these engines grow older, and in the near immediate future, the amount of work required to be done to maintain them in operation is going to show a substantial increase. The repair work to be done requires equipment that is not found in very many machine shops. To get the work done expeditiously, economically and properly, they need a shop of their own of that sort. Other concerns have found it necessary, and I would think that they should certainly have one by the time predicted, if not before.

Pipe lines generally provide these facilities because of the necessity of having their work done when the occasion arises to do it. If the repair of machinery is needed to get an engine into operation tomorrow or the next day, having some machine shop available to do it a week from some Thursday will not help you out much.

The commercial type of machine shop is not designed for this particular class of work. There may be some railway shops that would be equipped with machines for handling railway locomotives, and some manufacturing shops with equipment designed for the manufacture of their particular product; but no shops that I know of have the equipment designed for handling the specific character of material that this company has. Ordinarily, machine shops are not found in a county seat town, and even if they exist, my experience has been, when I was with the Ohio Fuel Supply Company, that we needed a shop of our own, and we built one practically right in the middle of a manufacturing district, in the town where some of our engines were manufactured. This was done for reasons of economy and for reasons of continuity of operation. By that I mean the saving of time to get a part which goes out of commission back into service.

Without referring to any other particular items shown in the exhibits introduced in connection with the testimony of the three witnesses, Strong, W. H. Davidson, and Powers, I have made a careful study of the schedules of additions to plant, replacement of plant equipment and maintenance, as well as operating charges, set forth in these exhibits and concerning which they have testified. In my judgment the sum of money set forth in these schedules of additions to plant, replacement of plant equipment, and the items of maintenance and operating costs are reasonable, and in the future course of events will actually be expended by these pipe lines in connection with their operation. I think in the
preparation of those schedules that allowances have
791 been made for various expenditures which could be
foreseen; but I do know that there are many contingencies arising that can't be foreseen and that some of these contingencies entail the expenditure of tremendous sums of money, and that no allowance has been made for that in the preparation of these exhibits. It is my judgment that the companies should have an allowance for contingencies above the amounts which they have estimated, because they estimated only the items which they could definitely foresee. This allowance for unforeseen contingencies should be not less than ten per cent of the maintenance and of additional capital items. (Motion by Commission Counsel and Counsel for Illinois Commerce Commission to strike testimony of Mr. Biddison denied.)

Cross-Examination by Mr. Slaff.

I have never prepared a list of cases in which I testified since going into private practice, but since 1928 I have testified in the Federal court at Fort Worth in the case of the Lone Star Gas Company involving their Fort Worth distribution properties. I have testified before the Railroad Commission of Texas in a number of cases involving both distribution systems and the gate rate for the Lone Star group of properties. I have testified before the Railroad Commission of Texas in the Laredo distribution case. I have testified in the State District Court at Austin, Texas, in the case of the United System, involving the Laredo rate, and in the case of the Lone Star Gas Company involving their gate rate; and in the case of the International Gas Company involving the Wichita Falls rate. I have testified before the New Mexico Commission in regard to the Albuquerque Natural Gas Company. That was a case involving the application of the state law as to pipe lines being common carriers. I testified before an examiner for the Federal Court of the Western District of Arkansas in the case of the Arkansas-Louisiana Gas Company involving the Texarkana, Arkansas, rates, and again in a case for them involving the proposed municipal pipe line for Texarkana, Texas. I testified in the Federal Court in a case with respect to the Community Natural Gas Company's rate for gas involving Royse City, Texas.

Of the cases in which I testified before the Texas Railroad Commission involving distribution plants, there were Wichita Falls, Denton, Sherman, Waco, Fort Worth, and Greenville, Texas, and a dozen or more similar communities which have had cases up before that Commission. I testified before the Oklahoma Commission in a case involving rates at Sapulpa, Oklahoma, in a case involving rates for Avant, Oklahoma, and in cases involving the distribution rates in twenty-six towns of the Community Natural Gas Company, an affiliate of the Lone Star Gas Company. That was in Oklahoma. I testified in the State District Court at Austin in a case involving the Public Service Corporation of Texas, as to their transmission properties and as to distribution properties in Perryton and Canadian. I testified in the District Court at Waco in three cases for Texas Cities Gas Company involving damages as a result of explosion and fire.

I will prepare a list of the cases which I have given to the reporter, as well as any others that I may find in my files, together with a list of the dates of my testimony. This will have to wait, however, until I am back in my office and have access to the information. I will have this information available at the next hearing at which I am present.

792 I was a joint author with Burrell and Overhold of Bulletin No. 120 of the U. S. Bureau of Mines on the extraction of gasoline from natural gas by the absorption process. I believe that was in 1916. About the same time, the same data essentially was presented as a paper before the Natural Gas Association of America. Then I had a paper before a joint meeting of the American Society of Mechanical Engineers and the Natural Gas Division of the American Gas Association at Shreveport about 1930 on some of the economic phases of pipe line design. I had a

paper before the Natural Gas Division of the American Gas Association at Dallas about 1927 on limiting factors for pipe line projects. I had a paper at the Memphis meeting, about 1931, of the Natural Gas Division of the American Gas Association on some of the economics of pipe line design, and I have had some later technical publications of one sort or another. I had a paper at the last meeting of the Natural Gas Division of the American Gas Association at Tulsa this year on the subject of "Fair Rate and Fair Return." The paper I presented at the Dallas meeting dealt with the cost of construction of natural gas pipe lines. This was about the year 1928. Two or three of the gas journals reprinted this paper.

793 R. M. BUSSARD, recalled by defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 4, 1939.)

When on the stand before, I testified that certain of the detailed studies concerning future costs for additions to plant, replacements of plant equipment, and maintenance and operation would be presented by the various department heads and that other of these figures would be presented by me. I have prepared exhibits showing the future expenditures not accounted for in the various exhibits brought in here by the department heads who have testified.

(At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company; General Expense, Taxes, New Business Expense; R. M. Bussard—Witness", with the request that it be marked for identification as an exhibit. At the direction of the Examiner the reporter marked such document Exhibit 116 for identification.)

I have Exhibit 116 for identification before me. This exhibit relates to the general expense, the taxes, and the new business expense of defendants. There is a detailed sheet on each one of the items for each of the companies, and a combined sheet for the three items I mentioned.

Page 1 of the exhibit relates to the new business expense of the Natural Gas Pipeline Company of America. Page 2 is a summary of taxes to be paid by the two companies, showing a column for each company and a total for the two companies. Both of these pages show the sums already paid out in that same connection down to and through the year 1938. The details of the figures summarized on page 2 for Texoma are shown on page 3, which covers that company's taxes from the years 1932 to 1954, inclusive. The same detail is shown on page 4 for Natural Gas Pipeline Company of America over the same period. On page 5 appears a summary of the general expense of the two companies, and the total or combined general expense. The supporting detail for Texoma is shown on page 6 of the exhibit and for the Pipeline Company on page 7 of the exhibit.

Going back to page 1 of the exhibit, the figures opposite the years 1932 to 1938 are the amounts of expenditures for new business that were incurred by the company during the years named and are taken from the books of the Natural Gas Pipeline Company of America. The figures opposite the years 1939 to 1954, inclusive, are our estimates of the future costs of this activity of the Pipeline Company. This department was originally named the new business division but its duties have been extended to include other activities. They merely maintained the name that it was given at the beginning. The estimates for the year 1939 are based upon the amounts of expenditure incurred to date, plus our estimate of the amount that will be incurred during the balance of the year. This estimate of the amount that will be incurred during the remainder of the year is based solely upon the amounts of payroll now being incurred by that department. That is the present payroll
794 at the current rates, with a slight allowance for miscellaneous materials and supplies used by the department. This is the normal allowance for such items. The advance in the first column as between the years 1938 and 1939 comes about by a non-recurring item of expense which was paid in 1939. The reduction which is shown in the second column between the years 1938 and 1939 results from an adjustment of salary expense for a part-time employee of that department. The figures projected from 1940 forward are based on the present status of that payroll.

The explanation of the circumstance that in the second column no amount is set out for the years 1952, '53 and '54 is that we do not expect to have sufficient gas to meet the full market requirements of the companies during those years. Inasmuch as this part-time employee is concerned with the marketing activities of the company, we felt that we would not be justified in continuing his cost through the years of declining sales volume and, therefore, we have eliminated that particular item of expense in the years named. In other words, the business will be getting less at the point when we are no longer in position to have gas with which to load our lines, and his services will no longer be required.

Turning to page 2, which is a summary of the taxes, and the detailed breakdown of the different taxes to which these companies are subjected, I point out that these taxes are based upon the present tax liabilities or present statutes levying taxes of the various kinds to which these companies are subjected, as applied to the personnel, the property, and the volume of gas to be produced and sold by the company as set forth in the studies which have already been introduced at this hearing. We have made no provision for any increase in the rates of taxes or any increase of levies of taxes, but have adjusted the computations to meet the existing statutes governing the levying of taxes.

Texoma Natural Gas Company is now subject to seven types of direct taxes, namely, ad valorem taxes, franchise taxes, gross receipts tax, unemployment tax (both federal and state), capital stock tax, old age benefit tax, and income taxes (both state and federal). The two items, seven and eight, are not projected in the future for the reason that the federal gasoline production tax is no longer in force, and the automobile license tax was simply an accounting matter in the year 1932. This latter cost is now reflected in the departmental expense rather than in the tax expense. It is a tax incident to the operation of the automotive facilities.

Texoma's item of franchise taxes relates primarily to a tax imposed by the State of Texas. In the years 1932 to 1937, inclusive, the company paid a very nominal tax on the basis that the principal amount of its business was interstate, and hence not applicable to the Texas tax. But the State of Texas now is engaged in litigation with some corporations relating to the amount of franchise taxes which these corporations are paying. As a consequence, we paid a higher franchise tax in the year 1938, taking into consideration some of the points raised by the State.

795 The fact that the tax declined after 1938 is principally a reflection of the shifting between the gas and gasoline revenues, inasmuch as these revenues have an effect upon the franchise tax. If the State of Texas succeeds in its

litigation, our franchise tax will be materially increased above the amount of $1,663.90 set forth in the schedule. They will also claim back taxes for those years when the nominal amounts of $93.50, $71.00, and so on, were paid. The $1200 in 1939 and thereafter is the company's interpretation of its liability. That amount is less than the State claims we should pay. On page 3 the caption "Total 1939-1954" should read "Average". This is a typographical error.

There is one tax to which Texoma is subject and to which Natural Gas Pipeline Company is not subject. That is the tax set out in Line 3 and is a production tax levied by the State of Texas, based on the value of the gas at the wellhead.

Questions by the Examiner.

The history of Item 9 on page 3 and the reason why that item starts up in 1940 and terminates in 1946 is as follows:

When we take into consideration the estimated income of the Texoma Company and the deductions which will be allowed under the existing income tax law, we find that Texoma is subject to an income tax, and then we apply the rate in the existing law to the amount of the taxable income. Texoma is a non-profit corporation. (Company Counsel made the following statement: Its business is to produce gas and deliver it to Natural Gas Pipeline Company at cost. Cost includes all expenditures, including bond retirements from year to year. The reason the tax is payable in those years and not other years is due to the rate at which the bond retirements are to be stepped up in the year 1940. All of the bonds will be retired by the end of 1946 according to the present maturities.)

Direct Examination by Mr. Morgan Resumed.

On page 4 of this exhibit I have enumerated the different taxes to which Natural Gas Pipeline Company is subject or has been subject, and have shown the amounts of taxes that have been paid down to and through the year 1938, just as I did in the case of Texoma on page 3 of the exhibit. These taxes have been projected for the years 1939 to 1954, inclusive, on the basis of the existing tax laws.

The Natural Gas Pipeline Company is subject to nine types of taxes at this time, if we distinguish excess profits from federal income tax. In other words, there are nine types if we say there is one type of tax which is called income tax and another type of tax which is called excess profits tax. Actually, they are both income taxes. Texoma does not have a pipeline permit tax, such as is shown on Line 3 of page 4. Texoma has not been paying any use taxes, as shown on Line 5. It is subject to such a tax in the State of Oklahoma, but has not had to pay any tax because its purchases for use in the State have not been sufficient to create a tax. The State of Oklahoma permits a $100 per month exemption.

On Line 8 is shown an item "Mortgage Registration". That had to do with the registration of a mortgage in the past and is not recurring. That is true also of the automobile licenses and miscellaneous taxes, which are subject to the same explanation as that made in the case of the same items heretofore paid by Texoma. The item shown in Line 11 as "Excise Profits Tax" is not projected for the reason that we do not anticipate that Natural Gas Pipeline Company will pay any excess profits tax in the future. The undistributed profits tax shown in Line 12 is no longer effective.

796 *Cross-Examination Interposed by Mr. Slaff.*

The federal and state income tax shown for Natural Gas Pipeline Company on page 4 is the result of estimated income less the allowable deductions under the existing revenue acts. The remaining income, which is called "Net Taxable Income", has been multiplied by the tax rate in the present federal revenue act, and also by the average rate that we have been paying in the various states. The explanation for the increase in 1947 and for five years thereafter of the federal and state income tax to about double what it is annually in the period 1939 through 1946 is in line with my explanation for the Texoma Company, where we show no income tax after 1946. This particular item of bond retirement under the contract between the two companies enters into the gas bill paid by the Pipeline Company, and when repayment to Texoma for that expense is no longer included in the gas bill, there will be no further expense imposed on the Pipeline Company for that item; hence, the taxable income will have an increase commensurate with the decrease in the expense, resulting in the increased tax after applying the effective rates.

Direct Examination by Mr. Morgan Resumed.

The total tax liability for the period 1932 to 1954, inclusive, aggregates $31,861,859.44 for the two companies.

The general expenses shown on page 5 are those overhead expenses of the company in connection with the operation of the Chicago office. They cover the payroll in the Chicago office, the rent, the materials and the supplies, traveling expense, telephone expense, telegraph expense, and other items that we incur in our Chicago office operations. The general direction of both companies is handled from the Chicago office. No part of the expense of the Amarillo office is included here. That expense is in addition to that of the Chicago office. In general, Natural Gas Pipeline Company of America pays all of the costs of the Chicago office, and then, while there are some expenses which it stands alone, the bulk of the expenditure is prorated partially to the Texoma Natural Gas Company. Twenty per cent of the expenditure is prorated to the Texoma Natural Gas Company. That determination was made before I had anything to do with it. I do not know why it was done that way. It was made by the management or by executive direction. When I made the estimate of expenses for these two companies, I simply took the accounting procedure that was in effect. I do not know why that percentage was chosen.

The first column of figures on page 5 has to do with the general expense which has been assigned and will be assigned to Texoma Natural Gas Company. The second column has to do with the expense which has been assigned and will be assigned to the Natural Gas Pipeline Company of America. The third column is the total.

The salaries projected in the first three classifications of general expense shown on page 6 are based upon the now existing amount of payroll costs without giving any reflection to any increase in wages or salaries to the individual man, and without reflecting any increase in the number of personnel in the Chicago office staff. It merely provides for the same personnel now employed in the Chicago office at the same salaries, and makes no provisions for increases.

797 The item "Office Supplies and Expense" is projected at slightly higher than the 1936-1938 average, but I note that there has been a steady increase in that item of expense through this three-year period. We feel that $1,450

is a very nominal allowance for this expense, particularly when we take into consideration the many additional reports which we have to make now but did not have to make a number of years ago. The unemployment tax, the old-age benefits tax, and other such items, have caused us a considerably increased amount of clerical work, and necessarily then we have to provide stationery, pencils, and other supplies for that type of work, and the stationery and printing, which is Line 5, is made up of that same type of expense and will require at least as much expenditure as we have made in the past three years. As a matter of fact, it has been projected at $23 less than the average for the last three years.

The item of "Legal Expense" may be divided into three parts. I will call the first part the company payroll. The company payroll part has been projected at exactly the level that now exists, without reflecting any increase in the payroll rate of the existing personnel and without including any additional personnel on the legal staff. As between the years 1938 and 1939 there is a difference in the number employed in the legal department. An additional man has been employed in the legal department in 1939 as compared to 1938, and that has been reflected in our estimate of payroll costs. The second part of the legal expense is created by the payment of the retainer fees of outside legal talent, and we have included in our estimated expenses the normal amount that we pay to this outside counsel. This refers to litigation in Texas and other states where the company is doing business. When I say normal, I have in mind the amounts that are reflected on the books of the Texoma Company, and I have studied the past payments that have been reflected on Texoma's books. The items of litigation are not the only legal costs incurred by Texoma. I meant that this item covers any character of legal service that is not performed by the legal staff of attorneys. The third item of expense under this caption is miscellaneous, for the various loose-leaf services, and other items which the legal department finds necessary in its business. This is in addition to law books, which are not included in the item of "Legal Expense." That voids any duplication with this office expenditure and equipment that we had the other day.

The item "Injuries and Damages" shown in Line 7 is just another way of saying workmen's compensation insurance required by the several states, and we have projected the particular item of expense under the existing law without reflecting any increase in the rate. The fact that the item increases from year to year is solely due to the fact that there is an increasing amount of payroll expense from year to year as more men are needed. The rates at which compensation insurance is procured depend upon the payroll directly, and the latter is an important element in the amount of workmen's compensation insurance which we have to procure.

The item of "Insurance" is classified in two parts, roughly; the insurance which relates to the property and the insurance that relates to the payroll. We have projected our payroll rates and our property rates upon the basis of the existing statutes relating to these particular insurance items. We have had to show some increase in expense because we have some additional property which will be constructed in the future, and we also have additional payroll as we hire employees to take care of this additional property. My reference to statutes means
798 the statutes in Texas and to that type of insurance the
rates for which are affected. Rates for ordinary fire insurance, and insurance of that type, are fixed by contract. In this estimate the contract rates projected are those which prevail at the present time.

The item "Rent" shown in column 9 refers to the lease between the Natural Gas Pipeline Company and the operators of the building in which the company offices in Chicago are located. The costs shown here are exactly in conformity to the existing lease and do not reflect any increases above the rates stipulated in this lease. They do not provide for any additional expense, and the space which we have to provide from time to time for certain matters, such as we are now providing for the Commission, and the expense thereof, is not included in this item of rent.

The item "Miscellaneous" is more or less of a catch-all account, in that the expenses which are not readily allocated to other accounts are included in "Miscellaneous". Our projection of miscellaneous expense is slightly higher than the 1936-1938 average, but I would call your attention to the fact that we have incurred practically $7,000 of expense each year within this three-year period which we used as an average. That is a rather indefinite class of expenditure. I have no specific way of determining the exact amount. It has been materially higher than $7,000 and has been somewhat lower than that amount.

The item "Traveling" covers the expense accounts of the executive staff and the clerical staff and the engineering staff when they are out of the Chicago office on the company's business. We have projected this expense at a few dollars less than the 1936-1938 average.

Going to the next item, "Telephone and Telegraph" covers the expenses we incur in connection with the services provided by the Western Union Telegraph and similar service. We project this expense at $15 a month more than the three-year average. This projection is less than the 1936 expense and a little more than the 1938 expense.

Drafting expense is incurred in connection with maps and plats and charts, and other items. I have shown an estimated cost of $10 more than the three-year average. This last item is increased by $10, which is a very nominal allowance and it would provide for very little paper or a very small tool that we might have to have in that time in that activity. I have no specific reason for thinking there will be an increase in expense.

The auto expense covers the cars assigned to the executive staff and has been projected at only $6 above the three-year average.

"Engineering and Research" is an item which is quite erratic and occurs from time to time, but we have projected it at only $8 in excess of the three-year average.

The item "Employees' Retirement Plan" relates to what is in effect a contract between the company and its employees. There is a life insurance company, which handles the funds accumulated under the contract. This contract between the company and the employees provides for pensions for these employees, and we have reflected the cost here in accordance with the provisions of the pension plan.

799 The increase between 1938 and 1939 comes about due to the fact that the plan was put in effect late in the year 1938. Therefore, 1939 is the first full year of cost on this item. The decrease in this item as we go from 1941 through 1942 and 1943 comes about because of the operation of the contract, under which by 1943 the company no longer has any obligation to pay to the insurance company any sums representing the cost of insurance covering past service as of the time the contract went into effect. All of these charges are in conformity with the contract.

Questions by the Examiner.

In Item 12, "Telephone and Telegraph", there is no Western Union lease mixed in that item. The lease expense in relation to Western Union is not in the general expense account of Telephone and Telegraph. My understanding of that particular item about which you ask is that it is located in the telephone department expense. There is no duplication involved there.

Among the various types of insurance which the company carries is a type called group insurance, which is a life insurance and a disability insurance, and the rates in the insurance contract are applied to the payroll of the company.

Direct Examination by Mr. Morgan Resumed.

Page 7 of the exhibit relates to the general expense of the Natural Gas Pipeline Company and is, in effect, the same kind of a page as page 6, relating to the Texoma Company. We followed the same procedure in determining the amounts shown along the respective lines on page 7 as we followed in determining the amounts shown on page 6.

(Thereupon EXHIBIT 116 was offered and received in evidence over the objection of counsel for complainant and the Commission who at the same time moved to strike this exhibit and all exhibits of a similar character, and the witness' testimony in connection with such exhibits. The objection and motion were overruled and the counsels for both Commissions were granted exceptions.)

Going back to Exhibit 116, there is no duplication between the item of "Legal Expense" as shown on line 6 on pages 6 and 7, and that shown in the exhibit offered through Mr. Campbell concerning regulatory expense. The legal expense, outside of the regular staff, connected with this case is not included in line 6 on pages 6 and 7 of Exhibit 116. This expense is included in the regulatory expense.

I have prepared a consolidation of the amounts to be expended, as determined by the economic study which others and I have conducted concerning the future operations of these two companies, which have been offered in evidence by the various witnesses here during these hearings.

(At this point counsel for defendants handed the reporter a document captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Summary of Additional Capital Expenditures and Operation and Maintenance", with a request that the Examiner cause it to be marked as an exhibit. Thereupon, at the direction of the Examiner, the document was marked Exhibit 117 for identification.)

800 Exhibit 117 shows the consolidated figures to which I referred in my testimony a moment ago. The exhibit is divided into two general parts, one relating to the capital expenditures and items incident thereto and the other part relating to the question and maintenance of the companies.

On page 1 of the exhibit we find the consolidation of the capital expenditures, the book cost of the property retired, and the salvage items of the combined companies. At the bottom of this page there is the word "Note" and following that an asterisk, after which the language "Includes 1938 carry-over as follows," and then some details. The explanation of this note is that certain construction work which had been started in 1938 was not complete as of the first of 1939, or the charges therefor had not come onto the books at that time. The work was finished during 1939, and the cost of completing the work was called the 1938 carry-over, which is a term which we use to indicate the fact that the work was incomplete as of the first of the year.

The department heads were requested to omit from their estimates any work incomplete as of January 1, 1939. Their estimates covered only work that was commenced on or after the first of January, 1939. In order to give a complete picture of the property requirements of the two companies, it was necessary that we bring in the expenditures made during 1939 for those items which were in progress at the beginning of the year; such items not being in operating department statement. The amounts shown here have come from the books of the company and are not estimates.

Page 2 of the exhibit is a summary of the capital expenditures of the Natural Gas Pipeline Company. The expenditures are shown by years from 1939 to 1954, inclusive, and are shown by the several operating departments of the company, and also by the automotive and furniture and fixture items. The first column is captioned "Exhibit No." and underneath that caption are the figures 97, 105, 112, 115, and 113. These figures refer to the exhibits that were offered by the various department heads, and they are placed here as a matter of identification. We thought this would assist anyone in understanding from whence came these figures. They occur through successive pages of the exhibit, and the same explanation is applicable to that caption and the figures underlying it wherever it occurs in the exhibit.

Page 3 of the exhibit is a summary of the book cost of property retired incident to the construction work of the Pipeline Company. The information is given by years and also by departments.

Page 4 of the exhibit is a summary of the items called salvage, which are accomplished in connection with the additional capital expenditures referred to previously. This sheet relates to the Natural Gas Pipeline Company. The figures are shown by years and by departments.

Sheet 5 of the exhibit is a summary of the capital expenditures of Texoma Natural Gas Company, and here again we have shown the figures by years and by departments. We consider the automotive and furniture and fixture items just as if they were departments within themselves.

801 Page 6 of the exhibit is a summary of the book cost of the Texoma property retired in connection with its additional capital expenditures. The figures are shown by years and by departments.

Sheet 7 relates to salvage incident to additional capital expenditures of Texoma, which we show by years and by departments.

Page 8 of this exhibit is a combined statement of the Natural Gas Pipeline Company and the Texoma Natural Gas Company, and is a summary of the operation and maintenance expenses which have been presented in several exhibits offered by the various operating heads, with the exception of one item. That one item is gas purchased from Colorado Interstate Gas Company. That is the first line of figures across the top of Page 8. These figures cover the cost of gas purchased by Natural Gas Pipeline Company from Colorado Interstate Gas Company, constituting one-fourth of the pipeline's requirements. The figures underlying the caption "1932" and successively through the year 1938 show the amounts of expenditure actually made during those years, and are taken from the books of the company. The figures underneath the captions "1939," "1940," and so on through the year 1954 relate to the costs which will be met in the future for the purchase of gas from Colorado Interstate. The rates are those now in effect, and the volumes are the results of the estimates presented by Mr. Kesinger. The prices are fixed by the existing contract.

Page 9 of the exhibit is a summary of the operation and maintenance expense of Texoma Natural Gas Company. These items have been presented in various exhibits that were brought in by the operating personnel, and we show the figures here by year and by operating facilities. We also show the figures for regulatory expense, taxes and general expense.

Page 10 of the exhibit is a summary of the operation and maintenance expense of Natural Gas Pipeline Company. Except for the item of purchased gas, these expenses have been presented in previous exhibits and are merely a consolidation and compilation of those figures.

The caption "Completion Cost of Work in Progress January 1, 1939, None" referred to in a note at the bottom of page 4 means that there is no salvage occurring in the year 1939 for the work that was in progress as of the first of the year. On page 2, the last column, the first figure under "Total 1939-1954" is $1,055,990.

(At this point EXHIBIT 117 was offered and received in evidence over the objection of counsel for both Commissions who moved to strike the exhibit and the witness' testimony in connection therewith. The objections and motion were overruled and the exhibit was received in evidence. The Examiner allowed counsel for both Commissions exceptions.)

(Motion by Commission Counsel and Counsel for Illinois Commerce Commission to strike portions of Exhibit 98 denied.)

---

802 G. M. DAVIDSON, recalled by defendants, testified as follows:

Direct Examination by Mr. Hedrick.

(August 28, 1939.)

My name is G. M. Davidson. I am the same G. M. Davidson who testified in this case at Chicago on August 3. Supplementing my testimony as to qualifications and experience, particularly with reference to the natural gasoline business, I spent twelve years directly in that business prior to joining the defendants. In the last four or five years of that twelve years, I was general superintendent of what is now Cities Service Oil Company, which had extensive natural gasoline plant operations. Since joining defendants, I have been responsible in an executive capacity for the operation of Texoma's Natural Gasoline Plant. I have been largely responsible for all negotiations in the sale of the product from this plant. I have kept informed during the past several years as to the going prices on the market of natural gasoline. I have prepared for presentation in this case information as to the prices which have been paid in the past for the purchase of natural gasoline. I am familiar with the revenues which Texoma has received for its gasoline and am acquainted with the places at which it has marketed its natural gasoline. I have an opinion as to the prospects for future marketing of that product. I am acquainted with the uses to which natural gasoline is put. This product is an extremely volatile gasoline. Most natural gas, whether produced with oil or as a dry gas, contains certain constituents which can be separated and liquefied, and these constituents are called natural gasoline. Natural gas, produced with crude oil, called casinghead gas, may contain from a fraction of a gallon up to twelve gallons of natural gasoline per thousand cubic feet. Dry natural gas generally contains about one-third of a gallon per thousand cubic feet. The average natural gasoline plant operating in the oil field, called a casinghead plant, will recover about two gallons per thousand cubic feet. The gas which is processed or handled at the Fritch plant is a dry gas. Normally the casinghead plants are operating on gas which is produced strictly with the oil with reasonable gas-oil rates. In the Panhandle there is a good deal of gas being produced from the stratas above the oil, not directly associated with the oil, but produced in the same wells as oil. This is called casinghead gas in the Panhandle. The gasoline which we manufacture is manufactured from a dry natural gas, and is the same gas which in turn goes into the pipeline of defendants.

In 1938 the natural gasoline production of the country was 5,800,000 gallons a day on the average. About 60 percent of this was produced in the Mid-Continent.

Natural gasoline is incorporated into motor fuel, and of the national motor fuel sold in the country in 1938, natural gasoline contributed 7.2 percent. Most of the natural gasoline produced is produced at casinghead plants, that is, plants processing gas associated with oil production. There is a very close relationship between the production of crude oil and the production of natural gasoline. That is to say, as the production of crude oil goes up or down, the quantity of natural gasoline produced in the country goes up or down. The gasoline plant operator contracts with an oil producer to treat his gas. They perform a service to 803 the oil producer in collecting the gas, and in redistributing the residue back to the leases for fuel purposes. The oil producer depends upon this service and he cannot afford to have many interruptions because it would affect his oil production. The quality of the fuel would change, and his apparatus, pumping engines, etc. would not be readily accommodated to the raw casinghead gas, or gas not processed for the removal of the natural gasoline, and he would suffer some loss in oil production. He is not willing to see many interruptions in the gasoline plant.

There is another factor contributing toward the continuous operation of the gasoline plant. That is the whole efficiency of these plants depends upon their continuity of operation. They cannot be interrupted at every price fluctuation of natural gasoline, because it takes time to get all of the distillation and fractionating equipment readjusted. Also, the gasoline plant operator cannot shut down because he would lose his experienced help and also his regular channels of market outlet. For those reasons, natural gasoline production is very closely related to the production of crude oil, and this relationship will hold regardless of price fluctuations.

In most oil production, though less true in the older fields, any field of recent origin will probably have a natural gasoline plant associated some place in the field with the oil production.

Natural gasoline can be produced by a number of processes. They are dependent upon pressure and temperatures. The larger number of plants are of the oil absorption type.

Going back to the relationship between the production of natural gasoline and crude oil, in the Panhandle field, and in other large gas fields, there is a relationship that exists between the production of natural gas and the production or manufacture of natural gasoline, because most of the dry natural gas produced in the country is processed for natural gasoline extraction. The carbon black plants in the Panhandle field, for instance, under the laws of Texas, first process the gas for the production of natural gasoline before burning the gas in the manufacture of carbon black.

The only market for practical purposes for natural gasoline is to refiners for blending with their gasoline produced from crude oil, so that all natural gasoline finds its outlet through the motor fuel market. It can not be used in its raw state as a motor fuel. The refiners of motor fuel use natural gasoline to improve its volatility and to increase its octane number. This use, however, has been gradually decreasing in recent years. There still remains a seasonable demand by refiners for natural gasoline, particularly in the fall months, but even this demand is decreasing. I know of no other market for natural gasoline, other than the use by refiners.

By the term "volatility," I mean an evaporating characteristic of the liquid. Ether has a low boiling point and a high volatility. Mercury would have a high boiling point and a very low volatility. Gasoline is composed of a number of hydro-carbons, all of which have different boiling
804 points. However, the relation of volatility still holds
by reason of more or less lighter fractions in the gasoline. Volatility can be gauged by distillation in an apparatus and procedure prescribed by the American Society of Testing Materials, and it can be gauged by its vapor pressure. Vapor pressure is a gauge of the total volatility of the product.

Octane number of the gasoline is a relative figure indicating its tendency not to knock when used in an engine. This octane number is obtained by operating a laboratory engine under prescribed conditions, with octane, a pure hydro-carbon, having a number called the octane number 100. All other fuels are referred to this octane rating, and depend upon the intensity of knock in this particular engine.

Many of the refiners are forced to use tetra-ethyl lead in their gasoline. However, they would like to avoid the use of this compound as it is extremely expensive. Natural gasoline having a high volatility and a high octane number is used by the refiner to increase the volatility and octane number of the products of his refinery. The necessity for the use of natural gasoline, however, is decreasing, as I have already stated.

Natural gasoline is quoted at two base points. It is quoted on a North Texas basis, and on what is called a Group 3 basis. North Texas are the quotations applying to all gasoline produced in New Mexico, Texas and Louisiana. Natural gasoline produced in Group 3 would include all that produced in Oklahoma, Kansas and Arkansas. The freight charges on a shipment of natural gasoline will be such that the gasoline produced in each of these areas will have its market outlet. I mean by that, that North Texas cannot economically ship to the Chicago market in competition with natural gasoline being shipped from Group 3. I want to make the point that it is obvious that the freight rate for the North Texas Group may be different for gasoline shipped from the Panhandle to the Gulf Coast than from the Gulf Coast fields themselves. There is a difference in the freight rate within the area, but it would cost more to ship natural gasoline from the North Texas area than it would from the Group 3 area to Chicago. This term "Group 3" was developed between the railroads and the oil industry. The only groups that we have to deal with in the sale of gasoline from our plant are Group 3 and North Texas. I can't answer the question as to what is Group 1 and Group 2; I have never heard of them; I don't believe that is in the Mid-Continent area, or I would have knowledge of it.

Natural gasoline prices are quoted in Platt's Oilgram daily. Those prices are based on natural gasoline of a specification known as Grade 26-70. I should say that these quotations are based on spot shipments for the day. I mean by that, all sales that were made outside of contracts existing between, say, a natural gasoline manufacturer, his marketer, and the refinery. There are a number of different grades of natural gasoline. All of them are referred to this one grade which is quoted, with a percentage differential fixed by agreement between the buyer and the seller and based on the quoted price for this grade 26-70. Grade
805 26-70 specifies a grade of natural gasoline which has a
vapor pressure of 26 pounds at 100 degrees Fahrenheit and a minimum distillation of at least 70 percent at 140 degrees Fahrenheit under the American Society of Testing Materials standards for distillation.

Ordinarily natural gasoline is shipped in special tank cars, equipped with an insulated jacket on them and with unusually large expansion domes on the tops of the cars. Some gasoline is shipped by pipeline, some as natural gasoline and some is put into the crude oil for transportation to the refineries and later distilled along with the crude oil distillation. The freight charges are paid by the buyer. The larger producers maintain their own sales organization and own their own tank cars. The smaller producers use the services of marketing companies who supply these tank cars, and find a buyer for the product. Generally, the natural gasoline manufacturer pays from ⅛ to ¼ of a cent per gallon, as a marketing charge, and in addition he is charged with outage and freight on outage and freight equalization, if any. In other words, if the price of natural gasoline is 3 cents, there would be a deduction from that price of this marketing charge, which ranges from ⅛ to ¼ cent per gallon. That is in the case of a small producer that is using a marketing agency; I was also speaking of an integrated company where the charge is probably interdepartmental and of no consequence.

We do not have a marketing organization, but deal through outside marketers. At the present time Texoma has two marketing organizations: Phillips Petroleum Company and the Columbia Gasoline Company.

By "outage" is meant the volumetric loss of the natural gasoline in transit. In spite of the insulated tank car, an outage percent occurs because of the increase in temperature while the car is in transit, and also because it is necessary to reduce the pressure in the car at destination by venting the car before it can be gauged. An average tank car holds 8100 gallons. The outage will probably average 50 gallons a car for the year around. In the summer, it may get up to 5 percent, or 400 gallons. The 50 gallons is a very rough average. It would range considerably less than that up to about 400.

"Freight on outage" is occasioned because the refiner or the buyer is paying the freight. He is charged freight by the railroad on the basis of the tank car capacity. If the car holds 8100 gallons he will pay on that basis. If he receives but 8000 gallons, there will be an outage of 100 gallons for which he will charge the natural gasoline manufacturer the freight on that volume loss.

"Freight equalization" is brought about when the normal outlet for the gasoline being shipped, say from North Texas to Gulf ports is closed. That is, the marketer cannot find a market in the normal competitive area for that group. Now if the marketer can find a market, say in Chicago, for his gasoline produced in Texas, then the gasoline manufacturer will absorb the difference in freight between Group 3 to

Chicago and North Texas to Chicago. Thus, in addition to the marketing charge of one-eighth to one-quarter cent per gallon, the manufacturer must stand or pay for the outage, freight on outage, and freight equalization, if any.

806 The reason for the decreasing necessity for natural gasoline in the refining of motor fuel is that in previous years natural gasoline was an absolute necessity for a refiner if he was selling a competitive grade of motor fuel. The improvements made in refining technique are so marked that there has been a decreasing necessity on the part of the refiner for the use of natural gasoline, with a consequent reduction in the price of natural gasoline. It is true that there is still a seasonable demand for natural gasoline in a few fall months, but I have already stated that such demand is decreasing. Through the remainder of the year the refiner purchases natural gasoline for its merit, but he will not pay any more for that natural gasoline than the cost of manufacturing his finished product. By this I mean, in saying that he will not pay any more for it, to include his purchase price and his own costs in handling natural gasoline.

For instance, a refiner, through all of the improvements which have been made in refining technique, is able to turn out a finished and acceptable competitive motor fuel, and he has another gasoline which he can bring up to the same specification with the use of natural gasoline. He will buy natural gasoline for the improvement of this product, but he will not pay any more for it than what his finished cost would be for the product which he can make with his own facilities. To state it differently, the refiner during the past few years, through increased efficiency and refining technique, is able to manufacture a product which is a substitute for natural gasoline, and he is able therefore to make a motor fuel of at least equal quality to what he formerly made when he purchased natural gasoline as a blending agent, and that motor fuel so manufactured costs him a certain amount of money, and he is not willing to pay more for the natural gasoline, as a blending agent, than it would cost him to manufacture the same quality of motor fuel in his own plant without the aid of natural gasoline.

The improvements in refining technique which have

5

reduced the necessity for using natural gasoline as a blending element have to do with the cracking processes recently installed. These include the tail gas recovery plants at the refineries, the reforming plants, the catalytic cracking plants, polymerization and hydrogenation processes, and the general improvements in fractionating at these refineries, besides the improvement which has been made in the quality of the crude being delivered to refineries. These improvements have the effect of enabling the refiner to increase the volatility and the octane number of his products.

The cracking process in general is the destruction of the heavy molecules into lighter ones, and in making a light gasoline from what formerly may have been fuel oil or gas oil, or something of that character.

A tail gas plant is in effect a natural gasoline plant operating on the uncondensed vapors at a refinery. The modern refinery will have the equivalent of a substantial natural gasoline plant operated in connection with its operations. Tail gas simply means what has heretofore been left over which the refiner was formerly not able to use but which he now processes.

807 A reforming plant to some degree is comparable to the cracking plant in that it changes the molecular structure of a liquid from a heavier liquid to a lighter liquid, making an acceptable motor fuel. Within recent years, in addition to the normal cracking processes which were dependent upon elevated pressures and temperatures, a number of processes have been developed which use a catalyst. In the process this catalysis has the effect of accelerating the breaking down of the molecules, and in several of these processes there have been rather remarkable results, particularly on the high octane values.

"Polymerization" process and the hydrogenation process are the reverse of the cracking process, in that they take the lighter molecules and re-combine them in a process which will make a gasoline. Hydrogenation process is quite comparable with the polymerization process in that it converts lighter hydrocarbons to the heavier and makes an acceptable motor fuel.

There has been a remarkable adaptation of all these improvements in refineries in late years. Trade journals such as the Oil and Gas Journal indicate the expenditure of a hundred million dollars already made by refiners for such improvements. I expect that these improvements will be accelerated. I have an opinion as to whether or not the decreased use of natural gasoline in the manufacture of motor fuel will have an effect on the volume of natural gasoline which will be manufactured in the future. Natural gasoline will be produced in the oil fields so long as the natural gasoline man can show a profit on his transaction. The contractual relationship between the natural gasoline manufacturer and the oil producer is such that with a decreasing unit price for natural gasoline the payment to the oil producer for the privilege of extracting the natural gasoline will decrease. Naturally that will contribute towards a larger profit for the natural gasoline manufacturer and he will be able to manufacture natural gasoline down to a very low figure.

In spite of the lower return to the oil producer the service performed by the natural gasoline manufacturer for the oil producer is still conducive to the sale of casinghead gas by the latter. The decreased necessity for the use of natural gasoline will have no effect on the amount of natural gasoline produced from the gas transported by the pipelines. This is true because the natural gas pipeline transmission systems process their gas to improve the efficiency of transmission, as well as because of the profit motive in their operation of natural gasoline plants. For instance, if the price of natural gas were cut down to a point where it was not profitable for a natural gas company to manufacture natural gasoline, it would continue to extract the gasoline, regardless of price, so long as we had a market outlook.

(At this point counsel produced a document, in graph form, entitled "Monthly Average Price of Natural Gasoline and U. S. Motor Fuel", which the Examiner directed the reporter to mark as Exhibit 119 for identification.

Counsel also produced a graph, entitled "Ratio of the Yearly Average Price of Natural Gasoline to the Yearly Average Price of U. S. Motor Fuel", which the Examiner directed the reporter to mark as Exhibit 120 for identification.)

I have prepared a graph showing the prices of natural gasoline in the past and the prices of motor fuel in the past. Exhibit 119 shows the monthly average price of natural gasoline and U. S. motor fuels. The source of this information is indicated on the graph as published

by "National Petroleum News". That is one of the trade journals of the oil industry. It shows an Oklahoma
808 price of motor fuel between January, 1919, and November, 1922. It shows the comparable price of natural gasoline for that period. The North Texas market was indefinite at the time and the point I am trying to bring out by these graphs can be brought out with the relationship of the Oklahoma prices within that period. The graph shows the predominant grades of natural gasoline and motor fuel being traded in since that time based on the North Texas market. For instance, you will note "Grade A-72-78 North Texas, Natural Gasoline, December, 1922, to September, 1924." At that time natural gasoline was being graded on a different system than it is today, but that grade was the predominant product being sold. The same applies to the motor fuel being sold since that time. You will notice the point that I was making, that the octane rating of motor fuels has been increasing and the grades specified in November, 1931, to July, 1934, were made on a 65 octane rating, whereas today the octane rating of the motor fuel being dealt in mostly is 70 to 72.

The types of natural gasoline under the heading "Sources of Information" on the left side refer to the top graph on Exhibit 119 entitled "Natural Gasoline" and the types of gasoline on the right side refer to the lower graph on Exhibit 119 entitled "U. S. Motor Fuel". The horizontal scale in both the upper and lower graphs is a time scale between the years 1919 and 1938, each inclusive. In each year we have 12 divisions for the months of the year and the initial for the month is plotted on the top line of the top graph. For instance, in March, 1919, the price of natural gasoline was 24 cents. If I am reading this correctly, for that same period, motor fuel was selling for about 18 cents per gallon. The vertical scale in both graphs indicates the monthly average price, for natural gasoline on the top scale and for motor fuel on the lower scale. These are prices, in the case of natural gasoline, at the gasoline plant, and in the case of U. S. Motor Fuel at the refinery, without tax or without freight.

It is very obvious that the price tendency has been downward from 1919 to 1938, inclusive. I would like to make one other point with reference to these graphs.

Within each year on this graph we have plotted a small circle which shows the average price prevailing for the year. That is true on the top graph as well as the bottom graph on Exhibit 119. For instance, on natural gasoline in 1919 the average price was approximately 23 cents, and in the same year for motor fuel the average price was 17½ cents per gallon. In the year 1938 the average price of natural gasoline was slightly over 2½ cents per gallon and for motor fuel the average price was slightly less than 5½ cents per gallon. The average price tendency for natural gasoline for the last seven years, as is shown on Exhibit 119, remains the same or has gone up.

Exhibit 120 shows the price relationship that has been existing between natural gasoline and motor fuels. It is expressed as a ratio of the yearly average price of natural gasoline as a numerator and the yearly average price of motor fuel as the denominator. For instance, with a ratio on the vertical scale of one, the price of natural gasoline and the price of motor fuel would be the same. The horizontal scale in this graph covers the same period of years as that for Exhibit 119, and the curve shown is the relation between the circle points in Exhibit 119. I call your attention to the period between 1920 and 1926. There is some variation in this ratio, but you will find that the price of natural gasoline was approximately equal to the price of motor fuel. In
809 that period the refiner had to purchase natural gasoline at a loss to him, because in addition to the purchase price itself the refiner had to pay the transportation and the handling cost at his refinery. Now you will notice that there is a decided increase in tendency to decline in this ratio to the point where for the year 1938 the ratio was less than one-half. In other words, the price of natural gasoline is now less than half the price of motor fuel. If the tendency of this curve continued it would indicate that the value of natural gasoline would soon be zero. However, I do not predict that that is going to occur. There is some price at which these refiners can purchase natural gasoline at some profit to themselves. Prior to the year 1926, the price of natural gasoline exceeded the price of U. S. motor fuel. Since 1926, the price of natural gasoline has been less for each year averaged than U. S. motor fuel. The average year

in question to which I refer is directly above the figures showing the year. It is on the line. There is no significance particularly in the slope of the line itself for the intervening period because the points themselves indicate the average for the year. I simply connected the points with a line. The ratio between natural gasoline and U. S. motor fuel, say in 1929, is shown directly above the figure "1929" and is approximately 97. That represents the relationship between the circles shown under the columns marked "June, 1929", of Exhibit 119 in the natural gasoline charts and the U. S. motor fuel charts. By motor fuel, I mean gasoline sold through service stations.

I obtained the average price for the year for natural gasoline and for motor fuel, shown on Exhibit 119, by computation of the average for each month, and adding these computations together and dividing them by 12. It is a numerical average of the monthly averages and not a weighted average on the basis of the fuel consumed. I believe these exhibits show decidedly that the value of natural gasoline to the refinery is decreasing. I have an opinion or judgment as to what price as a maximum will prevail in the future during the life of this project. My judgment is that natural gasoline will sell at some differential below the price of motor fuel in the future. I have stated that the average price which we can expect the refiner to pay will be that which will be not greater than he can pay on an exchange basis, that is without profit. It may be that in the future he will demand a profit. However, I have not taken that into account. I have used as the basis of my prediction a differential which will be at no profit to the refiner.

I have computed the cost to the average refinery for handling natural gasoline. I know that this cost will be 2.2 cents per gallon. Now the average price of motor fuel in the North Texas field within the period of 1931 to 1938, inclusive, is 4.85 cents per gallon. Deducting the 2.2 cent cost to the refiner for handling I arrive at a price for natural gasoline at the manufacturer's plant of 2.65 cents per gallon. I chose the price of motor fuel over the period from 1931 to 1938 because that is a period when we have had some wide fluctuations in the price of crude oil. It is a period when there has been an abundance of crude oil, which situation prevails today. In fact, there are more crude oil reserves in sight at this time than there ever have been. In 1929 or 1930 there was some 8 or 9 years' supply of crude oil in sight. Today that figure is 15 or 16 years, at the present rate of consumption. I see no apparent reason for the price of motor fuel to increase with this abundance of crude oil. I mean at least during the 16 years of defendants' life.

810 In arriving at the 2.2 cents, I have taken into consideration the freight cost to the refiner in shipping the natural gasoline between the natural gasoline plant and the refinery. I have included the refinery blending losses and the labor involved in handling the tank car, in testing it, and his overhead cost. The difference in price between motor fuel and natural gasoline in 1938 was 2¼ cents per gallon. The price of 2.65 cents, which I have testified to, is substantially the average price of natural gasoline on the North Texas market in 1938, which was 2.63 cents per gallon. Up until the end of July, 1939 the average price was 2.60 cents per gallon. These are the last full months on which I have the figures.

Texoma's plant is what is known as an oil absorption plant, originally designed to handle 190,000,000 cubic feet but we have put as high as 230,000,000 cubic feet a day through it. The average production would probably be 70,000 gallons daily. A 70,000 gallon plant would probably be rated among the first ten in the country and I think third in the Panhandle. I have prepared an exhibit showing the future revenues which Texoma will receive from the sale of natural gasoline.

(At this point counsel handed to the reporter a document entitled "Texoma Natural Gas Company Future Gasoline Recovery, Sales, and Revenue, G. M. Davidson, Witness," and at the direction of the Examiner the reporter marked such document as Exhibit No. 121.)

Exhibit 121 is divided into five columns, the first column showing the years between 1939 and 1954; the second column indicates the average recovery which will be made at this plant in gallons per million cubic feet on a 14.65 pound pressure basis. This recovery has been established on the basis of our experience for the past three years in which we recovered 326 gallons per million cubic feet. I have obtained the figures for the gas production of Texoma for the future from Moore County as one general area and from Carson-Gray area as the other and have included the Canadian River gas. That is the gas which we purchase from Colorado Interstate Gas Company, amounting to one-fourth of the requirements of Natural Gas Pipeline Company of America. I used the term "Canadian River Gas Company" because that happens to be the company which produces the gas purchased by us from Colorado Interstate Gas Company. This natural gas is delivered to the Fritch compressor station of Texoma and is processed for the extraction of natural gasoline.

Questions by the Examiner.

When I gave these other figures on the quantity of gasoline that would be recovered from dry gas and casinghead gas I was stating figures based on 14.65 pounds pressure.

Direct Examination Resumed by Mr. Hedrick.

The proportion of gas which Texoma will produce in the future will change between Moore County and the Carson-Gray area. In other words, a lesser quantity of gas will be produced from the Carson-Gray area and more will be produced from the Moore County area in the future than in the past. That will have the effect of decreasing the aver-
811 age recovery in gallons per million cubic feet. We
have established that we can recover 316 gallons per million cubic feet from the gas produced in Moore County, 347 gallons per million cubic feet from the gas produced in the Carson-Gray area, and 311 gallons per million cubic feet from the gas produced from Colorado Interstate Gas Company.

I arrived at the figures shown in the third column captioned "Volume Gas Through Fritch MCF/Year (14.65#)" from the sales for the future plus the fuel requirements of the system, plus the line losses, and also the handling or processing losses through the gasoline plant. The quantity of gas which will pass through the gasoline plant will be in excess of the quantity which finally reaches the market. I have heard the testimony of the witnesses who have testified as to the reserves of defendants. These reserves were computed on a pressure basis of 16.4 pounds per square inch. In Mr. Kesinger's testimony, his basis was 14.65 pounds. There is no conflict between Mr. Kesinger's and my own testimony on the pressure basis.

I arrived at the figures contained in the fourth column entitled "Sales Gals/Yr.", which of course means sales in gallons per year, by multiplying the volume output in million cubic feet times the recovery per million cubic feet and then deducting a processing loss at the plant of 4.1 percent, which is the loss reflected by our experience and is accounted for by the treating, transferring and loading of the product.

I arrived at the figure in the fifth column under the heading "Gross Revenue Dollars Per Year" by multiplying the sales in gallons times the price of 2.65 cents per gallon less 2 percent, which are the terms of our present marketing arrangement effective until June 1, 1940, and after that period I have deducted 3/16 of a cent per gallon to cover the marketing cost; that is, to cover all of the merketing cost not only the direct charge of the marketer but also the outage, the freight on outage and the freight equalization. The reason I did not deduct 3/16 of a cent from the first of 1939 until June 1, 1940 is that our present market outlet is with the Columbian Gasoline Company for 50 percent of the plant production. This natural gasoline is shipped in tank cars. The remaining 50 percent is sold to Phillips Petroleum Company at the gasoline plant by pipeline delivery, the pipeline belonging to the latter company, the pumping equipment belonging to us. The present marketing arrangement that we have is one that is exceedingly favorable to us. The only cost for marketing is a deduction of 2 percent of the volume being shipped to each of these companies. It has been brought about by a competitive situation which has existed between these companies. These contracts expire on June 1, 1940. I have a definite opinion that we will not be able to renew the contracts under such favorable terms.

My opinion is based on the circumstance that at the time of the execution of the contract covering the period ending June 1, 1939, Phillips Petroleum Company found itself short of natural gasoline and competed with Columbian Gasoline Company for that year on a basis which gave us the same contract which is now in existence. It was strictly a competitive situation. At the termination of this last contract we were busy with this hearing and at the
812 first opportunity after recess we contacted the Phillips Petroleum Company and rather forced the issue on a settlement for the following year's production. It was a question of either take it or leave it almost, and on such short notice the Phillips Petroleum Company could

not readjust their supply to any other source, so they accepted the renewal of the contract which had been made the year previous.

In this last deal with Phillips Petroleum Company, I formed an opinion that we are not going to renew that contract. The basis of that opinion is that on the occasion of the last renewal we gave them such short notice to say yes or no to the renewal of the previously existing contract that they could not readjust their source of supply. They came to us with a proposition whereby the marketing charge would be considerably greater. It was turned down. However, with another year in which to make arrangements for another source of supply for natural gasoline I do not believe they are going to renew that contract. Now with the Phillips Petroleum Company out of that competition I also know that the Columbian Gasoline Company are not going to renew their contract for the remaining half of our gasoline under that former basis. We have in the past paid as high as 5/16 of a cent for this marketing charge.

Cross-Examination by Mr. Slaff.

When I say "I know that Columbian is not going to renew its contract," I mean that that is my impression; I feel that strongly about it in my judgment.

Direct Examination by Mr. Hedrick Resumed.

(At this point EXHIBITS NOS. 119, 120 and 121 were offered and received in evidence, the latter over the objections of counsel for complainant and the Commission, who were granted exceptions. Motion by Commission's counsel and counsel for Illinois Commerce Commission to strike testimony connected with the exhibits denied.

At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Salvage Value as of December 31, 1954." At the direction of the Examiner, the document was marked Exhibit No. 122 for identification. Objection by counsel for the two Commissions overruled.)

I have prepared an exhibit showing an inventory of the salvageable materials and properties, both real and personal, which each of defendants will have on December 31, 1954.

Page 1 of this exhibit marked 122 for identification is a recapitulation of the salvageable material of Natural Gas Pipeline Company of America in the property which it owned as of June 1, 1939. The details of that sheet are set out in subsequent pages of the exhibit. On page 1 are shown Accounts Nos. 1000, 1002, 1005, etc. Those account numbers are carried forward for identification purposes.

This first page shows the total salvage value of the property, the cost to reclaim that salvageable property, and the net salvage value of the property in existence on June 1, 1939.

Page 2 is a recapitulation of the salvageable material of Natural Gas Pipeline Company to be added after June 1, 1939. I secured the information as to the additional property to be added after June 1, 1939 from the testimony and exhibits of those who have testified to that effect; namely, Strong, W. H. Davidson, W. T. Bulla, R. M. Bussard, S. E. Campbell, myself, Powers and Mr. Dickinson. In listing the salvageable property of these companies, I have taken into consideration replacements of present existing property. For instance, if a river crossing were taken out and another river crossing put in, that would be a replacement. Only net additions to plant are reflected in this exhibit.

813 Page 3 is a recapitulation of the salvageable property of Texoma as of June 1, 1939.

Page 4 is a recapitulation of the salvageable property of Texoma to be added after June 1, 1939.

Page 5 is a statement of the salvageable warehouse stock of Natural Gas Pipeline Company of America, the top items being as of June 1, 1939, and the lower items property acquired after June 1, 1939.

Page 6 is a statement of the salvageable warehouse stock of Texoma as of June 1, 1939.

On page 7 is a recapitulation of the salvage values as shown by pages 1 to 6, inclusive. I have simply taken the salvageable property of the two companies and added those together to get the totals here.

Page 8 shows the value of No. 1 heavy melting steel in the scrap market at Chicago, as quoted from the Chicago Journal of Commerce in dollars per gross ton of 2,240 pounds between the period August 31, 1925 and August 31, 1938. It shows at the bottom of the page that the mean average for the past 14 years is $11.50 per net ton, a ton of 2,000 pounds, and that the price prevailing on June 1, 1939, was $11.38 per net ton. A footnote at the bottom indicates that the value of mixed scrap, a combination of cast iron and steel, is valued in the trade at $2 per ton less than the value of No. 1 heavy melting steel. This deduction has been uniformly used throughout this period. These quotations from the Chicago Journal of Commerce, the market prices for No. 1 heavy melting steel, are as of the dates shown on page 8 at Chicago. By "gross ton" I mean a ton of 2,240 pounds, and by "net ton" I mean a ton of 2,000 pounds. In the exhibit I have used net tons, and the cost per gross ton is only shown for information purposes, and for the reason that that is the tonnage figure used in the Chicago Journal of Commerce. The term "mean average" simply means arithmetical average.

Page 9 shows the freight rates as they existed on June 1, 1939 for scrap iron and steel in minimum carload lots of 75,000 pounds from the shipping points along our pipeline, described as Station 1, Fritch, Texas, etc., to the market at Chicago, which is practically the only market for the scrap material available. In figuring freight rates when the material is shipped from Texas we used the Fritch freight rate of $7.20 per net ton. When the material would be shipped from Joliet, Illinois to Chicago, we used $1.06 per ton. When the property would be shipped from any of the other points shown, that is Perryton, Texas, Minneola, Kansas, and so forth, we used the freight rate applying to a mid-point on our line located as of Beatrice, Nebraska, Station No. 6, $4.40 per ton. We found that that is the average freight rate that would apply to the salvageable material that would be sold as scrap. By a minimum carlot of 75,000 pounds is meant that if you do not fill your car to that 75,000 pounds, you still pay the freight on 75,000 pounds.

Page 10 shows the market value of No. 1 scrap copper at
Chicago as quoted by the Chicago Journal of Com-
814 merce over the period from August 31, 1925, to Au-
gust 31, 1938. It is expressed in cents per pound and
shows the spread of prices. For instance, on the line
August 31, 1925, it shows a spread of 11.75 cents to 12 cents per pound. The 14-year average on the next to the bottom line shows that the average has been a spread between 8.53 cents per pound and 8.87 cents per pound. On June 1, 1939, there was a spread from 7.25 cents to 7.75 cents. We have used, in our salvage study, the average of 7.5 cents per pound.

Pages 11 to 102, inclusive, contain a breakdown of all the property shown in the recapitulation, pages Nos. 1 to 6, inclusive. Page 11 shows Natural Gas Pipeline Company Account No. 1000—Lands in Fee. We have listed the fee lands of that company on that page of the exhibit. Line 1 of this exhibit shows that at Compressor Station No. 2, located in Oklahoma, we own in fee 30 acres. We are going to sell the equivalent of seven and a half acres at a going value of $15 per acre. We will realize cash from this sale of $112, and the last column shows that the cost to demolish and clear the foundations on this site will be $3600.

Cross-Examination Interposed by Mr. Slaff.

We are going to give the other 22½ acres to whoever will buy them; we are going to sell the 30 acres and are going to receive from the sale of that acreage $112. The reason we will spend $3600 to demolish and clear the foundations on this site is that, upon advice from our legal department, we cannot leave this site in a hazardous condition because of the liability that we could incur before the sale, and they have advised us that it would be necessary to clear the site to eliminate any liability from this source. It will be sometime before we can sell this land after the property on it is salvaged. While it is in our possession we would still be liable. A reasonable estimate of how long it is going to be in our possession before we will sell it would be from a period of months up to five years; during that time we figure there would be a hazard in maintaining the property and leaving it there; that is the explanation of why we are going to demolish the property before we sell the land.

Direct Examination Resumed by Mr. Hedrick.

Page 12 shows the salvage cost of the railroad crossings of Natural Gas Pipeline Company at the 57 railroad crossings owned by that company.

Page 13 shows, under Account No. 1005, the main lines and the gate valves and other similar property of that company as of June 1, 1939. With a few exceptions, we have shown the length in feet of the main pipe-line, for instance, and the tonnage of that pipe. Where we were in-

volved with the weight, we showed it as pounds or tons. When we were involved with a percentage of the cost of thet product, we showed the cost of the product so that the percentage could be applied to that. That is on other pages of this exhibit and not this particular page. This particular page shows only the weight and in some instances the length of the pipe. Up towards the upper right hand corner, the words "not salvageable" occur. That information was secured from other witnesses who will testify as to that. In order to put this exhibit in one piece I conferred with those witnesses and from what they told me they would testify to, I put that information in here. Right below appears the terms $20 a ton, $15 per ton, and $5 per ton. $20 a ton indicates the total salvage value of 362.66 tons shown at the bottom of that page, which will be salvaged. The $15 per ton is shown under the column "Cost to Reclaim", and is the cost to salvage the equipment shown as a total of 362 and a fraction tons. Where the term "Not Salvageable" is used, we are not attempting to reclaim that property at all, but are leaving it
where it is. That particular segregation of data was
815 put in there only as a matter of interest because of
the large tonnage involved, and so as to account for it in summing up the salvage. The term "Net" between the caption "$15 a Ton" and "$5 a Ton" means that we will obtain the difference between the cost of reclaiming, $15, and the total salvage of $20 per ton, leaving $5 per ton net salvage value.

Turning to page 14, which is a continuation of Account No. 1005, under the last three columns appear the words "1138/Ton" "1106/Ton" ".32/100N". This is a typographical error and should have read "$11.38 per ton", "$11.06 per ton', and "$0.32 per ton'.

On page 16, the words "cor. ir.", on the first line, mean corrugated iron. The breakdown of the main compressor buildings, shown on the second line at $89,303, is shown directly below on the same page and the item of the auxiliary and other steel buildings at all stations, of $79,080, is broken down on pages 17 to 19, inclusive, of the exhibit.

The group of figures near the bottom of the page, the first one of which is "Station 2, Mississippi Valley Structural Steel Company, 68 x 168 x 28′ 9″" showing an original cost of $9,602, refers to the original cost of the salvageable material contained in the building alone. The next column to the right shows a 28 foot extension costing $2,435, which means that subsequent to the original erection of this building we added a 28 foot extension to one end. These extensions were all added in 1938, and of course prior to June 1, 1939. The original cost of the entire building, therefore, is the sum of $9,602 and $2,435, which is the total to which any percentage will be applied.

On page 22 the first line shows that at Station No. 2 we have two 15 horsepower General Electric 440 volts, 1,750 revolutions per minute, motors. The last line of that same group shows an item "2-40-50". This item is really a 40 horsepower motor, although this is more completely described in the valuation report which is to follow in terms of 40-50. We wanted to identify it so that it could be cross-checked for a more complete description. In other words, there are 2-40 to 50 horsepower motors.

On page 24, the top line, "48-1250 hp. Wor. Hor. G. D. Compr." means 48—1250 horsepower Worthington Horizontal Gas Driven Compressors. In the next line the initials "PIW" and the following initial in which there is a typographical error—that "D" should be an "O"—indicates the manufacturer, Petroleum Iron Works in one case, and O. A. Smith in the other.

On page 25, the initials in the first line, for instance, mean that we have 18 Cooper-Bessemer 175 Kilowatts generating plants, making a total of 2,250 kilowatts. Four lines below that, the words "Robbins & Myers" refers to the manufacturer of a generating set with panel. It is a motor-driven ignition set, a small unit. In the group of figures at the bottom of the page, the first line, the letters "C. P." stand for Chicago Pneumatic, a manufacturer.

816 Cross-Examination Interposed by Mr. Slaff.

Where I stated above that the figures in the first line show a total of 2250 kilowatts, the total should be 3,150 kilowatts. That will change the salvage figure from $11,250 to $15,750. The difference between $11,250 and $15,750 carries down into my first total of $18,499 and then into my final totals of $19,236 and $18,498.

Direct Examination Resumed by Mr. Hedrick.

On page 26, the first line, the abbreviation "Aux." means auxiliary. The letter "M." means main.

On page 27, fourth line, "Galv. Dom." means galvanized domestic.

Page 29, near the bottom, over at the left hand side, the figures "919,499" and "470,588" mean pounds. These figures are converted into tons in the first column.

On page 30, the first line means 2025 feet of 400,000 circular mil copper wire, weighing 1.24 pounds per foot. The next line means 70 feet of No. 0000 wire, 3-conductor, weighing 1.9215 pounds per foot. In the fourth line, the initials "DBRC" mean double braided rubber covered. In the seventh line below, the initials "TBWP" mean triple braided waterproof.

On page 29, in the column under "Total Weight," where I have 459.7 tons, there appears to be a comma or a blur or something right before the figure. That should not be there.

On page 34, the first line under the word "Oklahoma," the letters "BWG Cu." means B and W gauge copper wire. Cu. is the symbol for copper.

On page 40, the top line shows "Supercompressibility Apparatus: —" and right below that you will find the words "Special Gas Measuring Device." In mimeographing, this first line should have been put over two spaces. The "Supercompressibility Apparatus" was modified for further explanation by "Special Gas Measuring Device," which should have followed on the same line; and following "Supercompressibility Apparatus," there should have been a comma. There is no significance in the first line being set off by itself the way it is. In the second line from the bottom where it says "Dew Paint Instrument," and "a" should be an "o," and the expression should read "Dew Point Instrument."

Page 34 shows the entire salvage from the telephone system.

On page 42 occurs the expression "Total Salvage 30%." That should have read 20 percent. That 20 percent does not apply to the law library.

On page 71, the initials and abbreviations in the first line mean 1-300 horsepower, 60 cycle motor with compensator and breaker. Several lines below, there appears the item "2-Clark Eng. #2 Comp." et cetera, which means Clark Engine #2 Compressor. That "S. B." is an abbreviation for the size of the compressor cylinder, which is 6 by 20. The last line means one 8-½—that zero is a typographical error and it should be 8-½ by 12—Westinghouse steam air compressor. The amounts shown throughout the exhibit under the heading "Cost to Reclaim" were obtained from consultation with witnesses who are to follow, or they are based on my judgment and experience in a few cases, which I will explain later. The figures which express my own judgment are those in Accounts Nos. 1000, 1002 and 1008 for both companies.

817 Exhibit 56 is a picture of a typical compressor station on the main line. This one happens to be compressor station No. 6, located near Beatrice, Nebraska. It is rather unusual to have such a good road alongside of a station. All buildings and superstructures of all character have been treated as salvage, but there will still remain the foundations and pits for the buildings, the cooling towers, etc. The foundation for these buildings is about 24 by 30. I am referring to the cottages, at figure 17. These are concrete foundations that have walls 2-½ to 5 feet in height, with a center wall extending down the center of the building. They will have to be demolished to ground level. I should say that this picture does not reflect the additions which have been made in the plant to date; and when this plant is demolished or salvaged in 1954, there will be an average of 15 houses at each one of these stations. There has been an extension made to the cooling tower, shown as figure 12. There has been an extension on the main building, No. 1. There has been added a pipeline warehouse comparable to building 14, and there have been extensions on the garages noted as 16. In addition, there is a foundation about a foot high under these garages which have been extended since this picture was taken. This building is about 20 feet wide and now about 60 feet long, and the walls are about eight inches thick in this low building here. They are not made of reinforced concrete.

Now we have this elevated domestic water tank here at figure 15 which is supported on some concrete blocks which will have to be removed. They are about 18 inches square and are up above the ground about a foot or 18 inches. Now as to the pipeline warehouse, figure 14, this is a special warehouse to the extent that it is built to facilitate rolling trucks, and this foundation is elevated above ground practically four feet, and in some cases where the warehouse is on a slope, the walls get up to eight feet high.

This compressor station No. 6 is typical of other compressor stations, and the description which I am making of the work to be done is also typical of the other stations.

At one end of this pipeline warehouse we have a pit dug underground for the storage of pipeline rubbers and other material. This pit is about five feet below ground and 20 feet into the building itself. In addition there are two cross walls in these buildings which elevate an inside platform. This concrete foundation is about ten inches thick and is reinforced. At figure 13 we have typical pipeline pipe racks, and these have been extended since this picture was taken. To support these pipe racks there are numerous concrete blocks about 18 inches square and on about five-foot centers for a length of 40 feet. Then at the cooling tower we have a concrete foundation which now is 24 feet in width, about 100 feet long, and has a pit half of which is in this picture which is about 10 feet deep. There is some heavily reinforced concrete here including column supports for the tower itself.

Proceeding into the piping at figure 11, there are a great number of anchors to hold down the pipe from vibration in this vicinity. There are a number of anchors which cannot be seen in this picture, but I would say that there are about 25 or 30 concrete blocks, all of which extend above the ground a foot to four feet. We have in addition to that the main building which has been extended 28 feet more, as is reflected in Exhibit 122, and in addition at
818 Stations 2, 3 and 9 the building is 28 feet longer than that.
This building here is about 70 feet wide and has a basement extending half of its length down below ground about six or seven feet. There are walls running through this basement that are about 10 or 12 inches thick to support, along with the column foundations, the heavy type of building that we have here. It is very heavy concrete and rather difficult to break out. That pit would have to be filled up.

In the building itself the concrete blocks under these main units are rather massive affairs. They are about 15 or 25 feet in width, they are about 50 feet long and about 12 feet deep. They extend above the ground line approximately two and one-half feet. They are heavily reinforced concrete. Besides containing anchor bolts and the ferrules for the anchor bolts, it is chuck full of steel. They all have to be broken at least down to the ground line. We will have to get rid of the concrete by filling up the pits with it.

Going now to the auxiliary building, that structure is about 30 feet wide and approximately 130 feet long. It carries a foundation under it which has a 10-inch wall which extends clear around the foundation excepting at one end where we have a pit the width of the building and extending into the building 30 feet. That pit contains the pumps for the water circulating system. The floor line in this building is about 18 inches above the ground line. Then we have the two auxiliary units with a heavy concrete block under each of them about five feet wide and 18 feet long, and this block is under the engine and under the generators and has to be a very solid block to hold this engine from vibrating. Under the boilers we have a rather heavy foundation. It extends above the ground line about two feet. It is of reinforced concrete and will have to be broken out. Then we have the foundations under the machine tools in one part of the building. We have the foundations under the air receivers that will have to be broken out. Referring to the elevated water tank, at figure No. 9, this structure is reinforced concrete blocks about three or three and a half feet square. It extends into the ground about five feet, and then at the center, at the standpipe, we have a concrete block about eight feet square which extends up above the ground line 18 inches.

There is a pit under the building at figure 10, ten feet deep. This is a 10 by 10 sump house. At figure 6 we have a 30 by 30 concrete hot well which is 10 feet deep. The walls of this pit are about 10 or 12 inches thick and heavily reinforced: At No. 7 we have the foundations for the lubricating oil tanks. They will have to be knocked out. These are about 12 inches thick, five feet long, and they elevate the tanks about two feet above the ground. There are two such tanks. The office building is about 30 by 40 and is indicated by No. 4 on the picture. This is somewhat comparable to the foundation under the houses having a center wall throughout the building. In addition, there are some scrubbers located on the main line, not shown in the picture. These are heavy walled vessels and require a heavy foundation. The block under these scrubbers is about six feet wide and 18 feet long. No. 5 is the garage and warehouse for the station. This is a building about 24 feet wide and about 60 feet long. It carries a foundation about 10 inches thick and a concrete floor throughout the warehouse section of the building.

819 If some of these holes in the ground to which I have referred should become filled or partially filled with water and we should go off and leave the property in that condition, it would certainly attract the children across

the road and other places in the neighborhood. Counsel have advised us that it would be necessary to level off those places and fill up those holes to escape any liability from damages of that nature. This liability would continue so long as the company owned the property. As a construction engineer, it is my judgment that the figure of $3600 in the last column on page 11, which is headed "Cost to Demolish and Clear Foundations," would necessarily be expended in doing the work which I have described. This figure applies to each of the Stations 2 to 10, inclusive. On page 1 the total appears to be $32,400, while on page 11 it is $32,450; and under the caption "Cash from Salable Acreage," on page 1, line 1, Account 1000, the total salvage appears to be $3,488, while on page 11 this figure is shown at $3,538. The figures on page 1 are in error. The correct figures are shown on page 11.

At the bottom of page 11, opposite "Ottawa Warehouse Site, Illinois" is the sum of $50. This amount, in my judgment, represents the cost of clearing up one of these pipeline warehouse sites.

We worked all of these figures up in detail, so much for filling and so much for demolition. The details are shown in my working papers.

Referring to page 48, the last column, the first line shows the cost to demolish Compressor Station No. 1 of Texoma Natural Gas Company as $10,932. That particular station is shown on the picture marked Exhibit No. 92. This compressor station is practically three times the size of any on the main line. At the main building designated by figure No. 1, we have added, since this picture was taken, an extension to the building which will accommodate four more units, and the construction within this building is quite comparable with that which I have described on the main line. The auxiliary building is larger and contains larger auxiliary units.

The cooling tower has been extended, or, rather, we have built a new one altogether at the location of the cooling tower noted as figure 4 in this picture. This has extended the tower about 75 feet. The tower itself has underneath it a pit of a bigger character than those in the other stations. This station at figure 5 has an elevated water tank comparable with those on the main line. In addition we now have a new office building located just beyond the building marked 6. This is a building about 35 feet wide and 45 feet long, elevated above the ground about 3 feet. We are going to build a 200,000 barrel tank at that station. Under that tank, the foundations will be twice the bearing area at least of the ones that we have now, which should just about double their size as far as yardage is concerned. At the camp itself, shown as figure 7, we have added, since this picture was taken, ten more houses. Others are contemplated for the future. We have extended onto the garages shown in the picture and, in fact, have built a new one at the garage marked 8 in this picture. The foundations under these houses are quite comparable with those I described for the main line. We have the pipe racks and material racks located at figure 10, and these have been extended since this picture was taken. We also have a new pipeline warehouse located just beyond the warehouse shown as figure 11 in this picture. This is a warehouse comparable to the one shown and is about 30 feet wide and 40 to 45 feet long. It has an elevated concrete foundation.

820 In addition to all of the compressor station and pipeline equipment at the main line station at Fritch, we have this big gasoline plant, and all of the foundations and pits in this plant will have to be demolished and filled up. At figure 20, these absorbers have under them a block of concrete which is approximately 6 feet wide and 50 feet long, and is elevated above the ground 18 inches. They have holding-down bolts extending into this concrete to hold the absorbers against winds and other vibrations. At the right end of the absorbers is a pit about 20 feet deep, with reinforced walls, which extend above the ground line about 18 inches.

At figure 21 we have the refrigerating plant, the dehydrating plant, as some have been calling it, where we have concrete supports under heavy exchangers and reboilers. We have a building foundation at this point which is about 10 or 12 feet wide and 40 feet long.

At figure 22 there is a sump. That sump is about 30 feet square and 5 feet deep. That will have to be filled up.

At figure 19 we have the Clark engine room and the pump building. This building is about 30 feet wide and over 200 feet long now. It has been added to since this picture was taken. There are heavy concrete blocks under these engine compressors and there are heavy blocks under all of the pumps in the pump end of this building.

Referring to the distillation equipment at figure 18, we have numerous stills and fractionating towers in this area.

Also run tanks and accumulators, all of which require supporting foundations extending above the ground.

The cooling tower at figure 17 has been extended until it is probably twice the length that is shown in this picture. That would make the total length of that tower about 250 feet long. I am trying not to exaggerate these things, but that is the best of my recollection. Now this cooling tower is built quite comparable with the other cooling tower in the station and contains a pit in one end about 10 feet deep, and also numerous columns heavily reinforced to carry the cooling tower. The boiler house is a building about 40 feet wide and 60 feet long. Located in this boiler house we have a pit under one end which is 10 feet deep, the width of the building, and 25 feet long. This pit contains the water circulating pumps for the gasoline plant and other apparatus in connection with the boilers themselves. The floor of the building is elevated above the ground about two feet. In addition there are concrete foundations, bolts and so forth, under the two boilers.

At figure 16, we have the stack for the boilers, which is a concrete structure heavily reinforced and is something over 100 feet high.

At Figure 14, we have the office and laboratory which is being extended at the present time.

At figure 15, we have the gasoline plant warehouse and garage, which are quite typical of the station garages and warehouses described on the main line. When I say "main line," I mean the line of Natural Gas Pipeline Company of America.

821 The gasoline storage tanks located at figure 13 all have heavy reinforced concrete foundations under them. There are, as I recall, four walls extending lengthwise under each of the four rows of tanks. The length of these walls would be about 80 feet and the width about 12 inches, and there are a total number of 16 walls in there. In addition there is the foundation for the treating pump house, not shown on this photograph, and the foundations under the treating tanks just towards the site of the storage tanks in the picture. The tanks themselves are about 2 feet above the ground and the foundations extend around the circumference almost half of their height.

The pump house and tanks are at the rear end of the group embraced in No. 13. Surrounding this gasoline storage there is a dike which would prevent the flow of gasoline from any storage tank which broke in this area. This will have to be leveled down. I have described the large 55,000 barrel tank, which is No. 12, and there is little to demolish or to readjust after reclaiming the tank itself. At No. 23 we have five scrubbers and we are adding now three more. These are heavy vessels to stand considerable pressure and necessarily have to have big concrete foundations under them.

The loading rack, at figure 9, will also have some concrete foundations and steel to reclaim after the loading rack itself is salvaged. It is my judgment, as a construction engineer, that it will cost at least $10,932 to demolish and clear the foundations and to fill the holes which I have described.

On page 48 is shown the cost of demolishing and clearing the Dumas warehouse site. In my judgment, this work will cost at least $50. The next item is the Kingsmill warehouse site, showing the same cost for clearing. It is practically the same type of building as the Dumas warehouse. Down below is shown the Skellytown warehouse site, with a cost to demolish of $100. The Skellytown warehouse site will contain some houses and a pipeline warehouse. It is a larger camp than either the Kingsmill or the Dumas sites and, in my judgment, it will cost at least $100 to clear it. Those last two items are property which will be added after June 1, 1939, as shown on page 48 of this exhibit.

Account No. 1002, on page 12 of Exhibit 122 shows 57 railroad crossings that will cost $250 each to replace in their original condition in accordance with the crossing contract. We have agreed to remove all of the pipeline property from the right-of-way of the railroad. This involves the removal of the pipeline itself, the casing surrounding the pipeline under the road bed, the vents which are attached to each end of the casing, and the seal between the casing and the pipeline. The hole that is underneath the railroad tracks will have to be filled and tamped in order to restore the railroad right-of-way to its original condition. The same thing is true on the Texoma railroad crossings appearing at page 49. That company has seven railroad crossings. It is my judgment that in each instance it will cost $250 per crossing to do this removal work and put the property back in the same condition that we found it.

Account 1008, refers to the telephone system and appears
on page 34 for the Natural Gas Pipeline Company and
822 page 81 for Texoma Natural Gas Company. The lower
half of page 34 shows the cost of reclaiming lines. The

first item reads "Beatrice to Chicago, four wires C. B. & Q. poles," showing a distance of 623.07 miles, at a cost of $55 per mile, or a total of $34,269 to reclaim those lines. It is my judgment that such an amount will necessarily be expended in that reclaiming work. The next item shows $40 per mile to do the work, and some of the other items show $25 per mile, and $55 per mile.

The cost of reclaiming this wire will be dependent upon the amount of work that is necessary in removing the wire from the poles. On the C. B. & Q. system there is a great congestion of wires and a great many cross arms, whereas on the Natural Gas Pipeline system we have four wires on a single cross arm. On the C. B. & Q. system the Natural Gas Pipeline Company does not own the poles but only the wire. Care must be taken not to damage the property of the railroad. Page 81 of the exhibit, the telephone system of Texoma Natural Gas Company, shows in the middle of the page the cost to reclaim at only $19.50 per mile as against the cost which we have shown on page 34. That is due to the amount of work that is necessary to remove the wires from the poles of the Rock Island Railroad Company. They do not have the congestion that the Burlington has on the length of line between Beatrice and Chicago. We have only two wires in the first four instances in Texas and four wires in the last line of that particular group of figures. That makes a difference in the cost of reclaiming. Down at the bottom of the page is the cost of reclaiming certain wires that will be added after June 1, 1939, at $19.50 a mile. In my judgment, it will be necessary to expend that amount in order to reclaim this wire.

Somewhere in this exhibit, I have lost the page number, is the cost to reclaim certain engines with a considerable expenditure for that reclaim work. Page 13 of Exhibit 122, where I show that it will cost $15 per ton to reclaim certain of the items at the bottom half of the page, shows that. The explanation is that I have obtained these figures through consultation with others who are to follow on certain items of reclaiming salvage. These witnesses will testify on this point.

On page 84, the eighth line from the top, appears an item of $3,500 for reclaiming 175 well meter houses. Those are small galvanized iron buildings about 6 by 9 feet, sectional buildings which have a concrete foundation under them about 8 to 10 inches high and in which the lower girth of the steel structure is buried. We will have to knock them out and we estimate the cost of reclaim to be $20 each. That is also true as to the 197 well meter houses to be added after June 1, 1939, which is the second item from the bottom of the page.

I have obtained the information shown on page 24 concerning the cost of reclaiming the 1250 horsepower Worthington engines from other witnesses who are going to testify as to that.

On page 11, the first line shows compressor station No. 2 in Oklahoma, and the items below that under the heading "Location" show the other compressor stations and various fee properties that Natural Gas Pipeline Company owns. The second column shows the number of acres that will be salable as grazing or farm land, and the remainder, that is 22½ acres in the case of station No. 2, we consider to be ruined by the salvage operations and demolition that have gone on in clearing the site. This part of the 30 acre site will be ruined for farming and grazing purposes.

823 I am acquainted with the going prices for lands of a comparable character in the vicinity of these various stations and fee properties, and the figures I have set out represent my judgment of the going market value of that property. In the next column headed "Cash from Salable Acreage" the amount was reached by multiplying the number of acres by the market value per acre; in this instance by multiplying 7½ by $15. All the other items on that page were arrived at in the same manner.

The item entitled "Red Oak Warehouse Site, Iowa" shows 1,322 acres, and a cash value of $15. That site is on the edge of this small community, known as Red Oak. This site is not in the residential section but it is in the vicinity of the poorer dwellings of the town. It was a proper site for the erection of a warehouse in that it would not violate any of the aesthetic tastes of the people surrounding it, and it was also adjacent to a railroad. That $15 is, in my judgment, the going value of that property.

The next item is the strip on the main line in "Manon County," Iowa. That is another typographical error. It should read "Marion County." This property was purchased to prevent further coal operations in the vicinity of the pipeline. There was a strip mine operation which was approaching the location of the pipeline, and we found it advisable to purchase this 20 acres. My recollection is that that strip is 20 rods wide, or 10 rods on each side of the pipeline. It is located in an area where there is no farming and merely grazing land. It is a rough hilly country. When these strip mining operations are completed, it will leave the land in such shape that it is useless for any agricultural purposes at all. There will not be enough coal left in the strip we have purchased to justify any further coal mining operations, and the land could not be sold for that purpose.

The next item is "Joliet Regulator Station, 2 acres," followed by the item "Joliet Meter Station, 10 acres." The salvage value for this property is included in the sale of the buildings at these sites and is shown on page 38 of the exhibit. Those buildings are of brick construction, plastered interior, transite roof and are excellent buildings. They cannot be moved economically, but we believe they have some sale value and we have included within the salvage value of the buildings at the meter station and regulator station the fee land which will be sold along with the buildings.

On page 12, Account No. 1002, under the caption "Right-of-way," no salvage value is shown. Our right-of-way grants give us the privilege of locating the pipeline on the property just so long as gas is being transported. On the cessation of operations, we will have no further rights in the property. It is simply an easement privilege granted the pipeline company by the landowner. At page 49, no salvage value is shown for the right-of-way of Texoma for the same reason. This exhibit contains no page 58 and no page 83. This is due to typing and putting the pages together.

At page 48 is shown the Compressor Station No. 1 of Texoma, which site contains 80 acres. In my opinion 60 acres of that will be ruined for farming or grazing purposes, and the remaining 20 acres can be sold for about $15 per acre, or a total of $300. The Dumas Warehouse site has 10 acres and only 2.5 acres will be salable at a
824 price of $15 per acre, netting our company $38. The Kingsmill warehouse site contains 11 acres of which 2.8 acres will be salable at $15, netting our company $42. The Skellytown warehouse site of 10 acres can be sold only to the extent of 2.5 acres at $15 per acre. At Dumas, an additional 2.6 acres will be added to the site and only .6 of an acre will be salable. This portion will sell for $15 per acre.

Cross-Examination Interposed by Mr. Slaff.

I have investigated the sales of property in the vicinity of each of these properties and I have knowledge of the going value of the property at each one of these stations. I obtained this knowledge from superintendents of these stations and know that the figures are within reason from transactions which have taken place. I have never appraised any land or real estate. (Counsel for defendant concedes that the witness is not a real estate man.)

Direct Examination Resumed by Mr. Hedrick.

On page 11, I have set out a number of particular properties. Other properties not owned at the present time will be acquired in the future but are not shown at that point for the reason that they will have no salvage value. I refer to the testimony of Mr. Strong who showed that we will have to acquire some more property on the Natural Gas Pipeline Company system. These acquisitions will be made necessary to protect the pipeline against strip coal mining operations and the same situation will obtain as to these new acquisitions as that already explained with reference to the strip we acquired in Marion County, Iowa. There are several other small properties now at meter sites and regulator sites along the main line. These sites are so small and isolated and so located that we believe they can be turned back to the farmer without cost to us. I would say these sites range from about 50 to 80 feet wide and up to 100 feet long. They are usually located in the middle of somebody's farm in the country.

Cross-Examination Interposed by Mr. Slaff.

In our figures for total salvage and for cost to reclaim thoroughout Exhibit 122, we have used labor and material prices as of June 1, 1939. I am not prepared to predict that these prices will exist at December 31, 1954. I do not profess to give an estimate of what prices will be at December 31, 1954. (Motion by Commission Counsel to strike so much of the witness' testimony as dealt with the cost of reclaiming and with salvage of property not now in existence. Ruling reserved on Motion.)

Direct Examination Resumed by Mr. Hedrick.

At page 24 of Exhibit 122, the item "48 - 1250 h.p. Wor. Hor., G. D. Compr,," the sum $88,247 was reached by multiplying the total number of tons 9,408 by $9.38 per ton. The figure shown on page 57 for the 15 - 1250 Worthington Engines was arrived at in the same way. The next line, on page 24, "19 - PIW & ADS Scrubbers," the total of $4,324 was arrived at by multiplying the number of tons, 380, by the salvage price of $11.38 per net ton. That is true as to the 5 scrubbers shown on page 57, and the other scrubbers shown on that page. The Worthington engines will sell as mixed scrap for $9.38 a ton and the scrubbers will sell as plate steel or heavy melting steel at $2 a ton more. The prices are those at Chicago, as already stated.

825 I have already stated that we used an average freight rate for the reclaim of main line material. That freight rate being $4.00, comparable to the freight rate from Station 6 at Beatrice, Nebraska. That rate was applied to all material reclaimed on the main line except at Joliet and Fritch. In addition to the freight charge we have a handling charge of $3, which includes the cost of loading into the trucks, the hauling into railroad shipping points and loading into railroad cars. That is the average cost and was applied throughout all of the reclaim exhibit, regardless of the mileage from the place of salvage to the shipping point. Most of the expenditure, of course, goes in the loading and unloading of trucks. The amount of hauling itself is very small. It will be about 5 to 7 miles on the average. The distance will not affect the cost to any appreciable extent. This $3 charge is based upon our experience in hauling up and down the line. We paid in 1935 or 1936 $5 per ton for hauling some of these Worthington engine units. We think we can haul the salvage for $3, however, because we have in mind breaking up the units into very small pieces which will be easier to handle. This will reduce the cost of hauling.

At page 57 the cost of reclaim for the 15 Worthington engines is shown at $44,688. There is a difference in the freight rate from Fritch, where the freight rate is $7.20 a ton, to Chicago. This makes the cost of reclaim of the Texoma property, which is figured on the Fritch rate, for salvage $15.20 per ton as against the $12.40 average on the Natural Gas Pipeline Company property from Gray, Oklahoma to Station No. 10. All other reclaim charges are figured at the same rate for Texoma property at and beyond Fritch as for the main pipeline property. The $15.20 is broken down into $7.20 a ton for freight, $3 a ton for handling, and $5 a ton for demolishing or breaking up the heavy parts into smaller pieces which can be handled to advantage. Included in the figure of $116,659, shown on page 24, is a $5 demolition cost per ton, and that same demolition cost is included in the cost of reclaim on page 57 on the 15 engines shown there. This figure of $5 per ton demolition charge I have obtained through consultation with other witnesses who are to testify. The figure of $5,472, shown at page 24, is broken down into freight $4.40, the same handling charge of $3, and in cutting up this class of material we will have a demolition charge of $7 per ton, making a total cost of reclaim of $14.40 per ton.

The second item on page 57 shows the cost of reclaiming 5 scrubbers will be $1,803. This figure was reached by applying the freight rate from Fritch, $7.20, the $3 handling charge, and the same demolition charge of $7, making a total of $17.20 per ton. The difference between the cost of reclaim of the scrubbers at Fritch and the scrubbers on the line of Natural Gas Pipeline Company is accounted for by the difference in freight rates. Throughout this exhibit where any heavy melting steel appears it is given a salvage value of $11.38 per ton. Where the material is mixed scrap it is given a value of $9.38 per ton. I obtained the figure of $7 per ton for demolishing material which will have to be cut by torch, through consultation with other witnesses who will testify on that point.

826 I used the expressions "mixed scrap" and "heavy melting steel" in designating the salvage material. The difference is there is no cast iron in heavy melting steel but there is cast iron in the material classified as mixed scrap. The figures opposite the line near the bottom of page 24, referring to 9 scrubbers, 8½ tons, $97, $122, $25, and the next line showing one 5 foot by 75 foot water gasification tower, at Station 10, 135 tons, and so forth, should be reversed. The 9 scrubbers weigh 135 tons, and the gasification tower weighs 8½ tons. The figures should be reversed clear across the four columns.

At page 24 of the exhibit, the net salvage figure of $28,412 and, at page 57, the net salvage figure of $17,111 are shown in red figures; that is the cost of clearing the property. The reason this property will be salvaged under such circumstances is that we can not abandon this equipment in place for the reasons already stated. By shipping this material to Chicago, we will derive a gross salvage of $88,247, and thus reduce the cost of salvaging the property referred to on page 24 to $28,412. The reason we can not leave this class of equipment exposed is that it would constitute an attractive nuisance if left on the foundations. It would also make it impossible to sell it along with the land still usable for agricultural purposes.

(At this point counsel produced a picture marked on the back "No. 1154, Fritch, Texas Station, 12, 24 by 36, 1250 HP Gas Engines" and requested that it be marked as an exhibit for identification. At the direction of the Examiner, the picture was marked Exhibit 123 for identification.)

Exhibit No. 123 for identification is a view of the interior of the Fritch Compressor Station at a time when there were 12 engines located at that station.

Question by the Examiner.

On the back of the picture referred to the words "Natural Gas Pipeline Company of America" have been stricken and the term "1300 horsepower" has been changed to "1250 horsepower", the real rating of these engines.

Direct Examination Resumed by Mr. Hedrick.

The equipment shown in this picture would attract all the children of the neighborhood, farm children or children from nearby communities, to play "Engineer" or what not around it. I have children of my own and I think I know what they are inclined to do. Now if they ever got into this equipment they would be exposed to all of the pits that are under the cylinders and under the flywheels. That flywheel weighs 25,000 pounds and is 15 feet in diameter. It extends above the floor line about ten feet, and the pit under the wheel is about five feet deep. There is an opening down through the engine, underneath the flywheel, which a child climbing up on top might fall down through. There is danger that a child playing on top of that engine would fall off the engine around the cylinders. The footing is very insecure at

any place where the child could stand. The cylinders are round and there are many protruding parts of the equipment. The equipment is liable to be oily and greasy. It is painted and kept in a rather polished condition. In fact some of our own men have been hurt falling off of this equipment, as familiar as they are with it. In one case a boy broke his leg. I know it is dangerous
827 enough that it has played hob with our safety record.

There is a basement underneath this building that extends from end to end and covers the viewer side of this picture, that is, over to the center columns. This basement is dark and there are low-hanging pipes. Somebody is bound to get hurt down there if they ever go down there and are not familiar with what they are doing. There are children in the small community of Fritch within sight of the Fritch plant. The population is scattered, but I would judge it to be about 500 people. Many of them are ranching people in that territory. Many of the compressor stations are situated where schools are located within sight of the station itself, and I know that there are many children passing by the plant site on their way to school. I have known of two or three instances, when I was working for the Empire Companies, where children and other persons were injured on property left in an unsafe condition. I will give you two or three instances.

While I was superintendent of a gasoline plant on a Cities Service lease known as the Bell and Dixon lease, near Okemah, Oklahoma, a lease was abandoned at the edge of this field, and the only piece of equipment left, after tearing down rigs and filling the slush pits and so forth, was a 500-barrel tank. There were several children playing in this tank, attempting to swim and enjoy themselves, and a 9-year old boy was drowned in it. They sued the company that originally owned the lease. I am familiar with another incident on the Cities Service refinery operations at Cushing, Oklahoma. The plant was abandoned and a watchman was left on the site. However, some children were playing in the yard of the site, throwing rocks in the cooling tower pond, and running around the pit. One of them slipped into what was formerly a cooling tower basis. This was quite comparable to our own cooling tower pits except it had a 45 degree sloping side. This boy attempted to get out of this pit but the algae growth on the concrete surface prevented him from getting out and he was drowned. There was another instance that I am familiar with, which occurred on the Cities Service Gas Company's system near Hominy, Oklahoma. The company had temporarily abandoned a compressor station, and had gone so far as to board up the main buildings. The units were not entirely unlike our own. Children broke into this building after removing the boarding from the windows and were playing apparently in the building, running around it and climbing columns and what not. They found a box of dynamite caps. These are a very small article, about the size of a lead pencil eraser. They had been put away in a place where the operating men thought no one would promiscuously pick up this dangerous article. In fact, it was put up on top of a rather high cabinet, but these children found these caps and in playing with them one of them had his hand blown off. The company was sued for $3,000 in that instance. I can't tell you what the final outcome of those suits was.

I am not interested alone in what this might cost the company but I would feel that I had not fulfilled my responsibility unless these hazards had been removed because of the danger to the lives of children.

Near the top of page 13, appear a number of items shown as "Not Salvageable". The gross value that we can obtain for this pipe is $11.38 per ton, for No. 1 heavy melting steel. The average freight cost in getting this steel to Chicago would be $4.40 per ton, a figure that I have already explained. After this steel is delivered
828 into Chicago, it will cost $4 additional to reduce this pipe to open hearth sizes. By "open hearth sizes" I mean a steel plate with a dimension 18 inches wide and 5 feet long. It cannot be sold as scrap without breaking it up in addition to cutting it in certain lengths for shipment. Pipe will have to be cut up into such dimensions that it will lay flat and be not over 18 inches wide and 5 feet along. If we add those two costs we would get a total of $8.40. Now if you deduct that cost from the price for material sold as scrap, $11.38, we would gross $2.98 delivered at Chicago. Now there are many other costs involved in salvaging that material other than the freight and the cutting into open hearth sizes. Obviously we would have to remove this pipe from the ditch. This

would cost a total of 62.8 cents per foot, or $15.14 a ton, since the pipe weighs approximately 83 pounds per foot. From these figures we reach the conclusion that it would not be at all profitable to attempt to salvage those items. On the same page there is a cost to reclaim certain gate valves of $15 per ton. We have estimated that it will cost $15 per ton to salvage all pipe material, including the gate valves and other pipe fittings referred to at the bottom of that page. We had the same hauling cost that I have already referred to, $3 per ton, and a salvaging operation cost of $12 per ton. That salvaging or reclaim cost of $12 per ton will be covered by the testimony of other witnesses in this case.

Cross-Examination Interposed by Mr. Slaff.

We included in the estimate of $15.14 per ton for cost of reclaim, the ditching, cutting into 40-foot lengths, stripping the couplings, raising the pipe from the ditch, back filling, hauling and loading on cars, hauling excess dirt for the back-fill, cleaning pipe, and the labor cost in handling the pipe while cleaning, the average cost for damages, supervision, taxes and insurance. The figure is the average cost taking into consideration conditions as they exist up and down the line.

Direct Examination Resumed by Mr. Hedrick.

Referring to pages 30, 31, 65, 66 and 77 of this exhibit, the material shown in the group at the top of the page is scrap copper. It is generally insulated copper wire. That represents a salvage value of 7.5 cents per pound, or $150 per ton, for copper. The next column shows the cost to reclaim at $44 per ton. The figure should be $44.40 per ton; and in the next column where the net salvage is $1,816, or $106 per ton, the figure should be $105.60 per ton. In the preparation of the exhibit the even dollars were used instead of the cents out on the end, which will make some small difference in multiplication. The money figure is correct with the changed figure to which I have referred. I arrived at the cost to reclaim through consultation with other witnesses, who are to follow me. This cost is broken down into freight of $4.40, and 2 cents per pound for handling costs. The latter item includes the collecting of all of this insulated copper wire and burning the insulation from it, and the haul to the railroad. That is true with reference to all of this insulated copper wire shown on the pages above mentioned. In order to sell this copper at the prices stated, it is necessary to take off the insulation and wrappings so that it can be sold as copper, the price being for pure copper.

On page 31 there is another correction. The second group of figures from the top of the page shows $279 and a total of $2,869. Those figures should be pounds instead of dollars.

829 On page 38 of this exhibit, down at the bottom of the page is a group of figures showing the cost of certain structures at Joliet. These include meter station buildings, described under that heading at a cost of $70 for the by-pass meter house; and a brick garage at a cost of $2,014; the office, laboratory and meter house, brick transite roof at a cost of $11,842; and a well house at a cost of $910. There is also shown still lower down certain regulator buildings at a total cost of $11,987. I have an opinion as to the amount which these buildings could be sold for at this time if they were of an age that they will be on December 31, 1954. This opinion is based upon my own experience in my former employment with the Empire Companies, and experience I have had in selling buildings of this particular type. These are substantial buildings. They are of brick construction and for a specific pipeline use. They are not readily adaptable to reconstruction into houses, but we feel that we will be able to sell this property for 10 percent of the costs that we have in the buildings themselves, including the 10-acre tract of land on which the buildings are located. This 10-acre tract of land has never been farmed. It is in a wooded section 4½ miles west of Joliet. There are no residences in the immediate vicinity. We had to build a private road into the property. That property is what might be ordinarily termed as scrub oak country. There are scrub oaks on that site. The soil is yellow clay but it will grow crops to some extent. Nobody has ever found it advisable to farm it. The trees on the property, I would say, are about 40 years old. The regulator site of 2 acres is a very small tract on a hill side, rather rocky. That is, the rock comes practi-

cally to the surface. We have attempted to grow a lawn on this place and have had difficulty, but it looks all right.

Referring to pages 41 and 91 of the exhibit, we show certain automative equipment showing a salvage value of 30 percent in each case. I have a judgment, based on my own experience in purchasing and selling automobiles, of which I have direct charge for defendants, as to the salvage value of the automobiles, trucks, trailers, and other automotive equipment, which these companies will have on December 31, 1954, taking into consideration the average age of the equipment at that time. Those cars will be 18 months old at the time as an average, and although we are obtaining from 40 to 60 percent of their value on trade-in for new equipment, we could not get that on a cash sale. I believe we will be able to get about 30 percent of their original cost.

On pages 34 and 81 of the exhibit are shown the telephone systems of the two companies, respectively. I have already testified as to the cost of reclaiming copper wire. The salvage value is based entirely on the 7½ cents per pound price at Chicago, which is shown as a part of the exhibit. In addition to this copper wire, there is an item of $511 shown as the salvage value of certain telephone equipment to be added after June 1, 1939. We do not believe that there is any other salvage from the telephone system than a net salvage $97,068 for the telephone system of Natural Gas Pipeline Company of America net salvage of $15,521 for that of Texoma Natural Gas Company and an additional $511 for equipment added after June 1, 1939. We have other features of construction which were given consideration, for instance the poles, the cross arms, and the pins, the insulators, the guys, and the anchors, radio equipment, repeaters, test sets, and all of this we felt had no value whatsoever on reclaim. These are light poles, 5 inches at the top, 20 feet high, and they cannot be moved. The butts will all be rotted to the point where you cannot cut the 5
830 feet off and get any salvage for a 15-foot or a 14-foot
light pole of that character. The telephone poles are on the south half of the system. They are not in one place and would have to be picked up and loaded at some expense for hauling charge. The other equipment which is commonly referred to as "pole hardware" would not sell for the cost of reclaiming it. I am thinking particu-

larly of the insulators. These insulators are packed like eggs in an egg crate when we receive them and with the best of handling we break about 10 per cent of them on construction. It would be necessary to take these insulators down, many of them would be broken when we would detach them from the pins. We would have to make this arrangement for repacking them and that cost would just exceed anything that we could get out of them. The same would apply to the pole hardware, such as braces for the cross arms and the bolts that are screwed into the poles to hold those arms, and so on. Although the voice repeaters and the ringing equipment which Mr. Bulla referred to will serve our purpose, probably, until the end of the project, the chances are that there will be no resale of this class of equipment at all. They are built with radio tubes, transformers, and relayers and a lot of the small telephone equipment that we have seen on the telephone switchboards. I am sure they would be obsolete by the end of defendants' life. We own a limited number of telephone and test sets, but these will not be reclaimable and will have no value. This equipment will be from 15 to 20 years old at the end of 1954.

As to the radio equipment, we would have to find a buyer. Comparing it with existing conditions, I don't know who would buy that class of material. We have obtained a special permit to operate on a specific wave length from the Federal Communications Commission, and this equipment is not adapted to any amateur or other commercial work that I am familiar with. The radio equipment which we will have at the end of 1954 will be from 5 to 7 years old at that time.

Referring to page 16, and the breakdown on pages 17, 18, 19 and 20, those buildings and houses referred to on those pages will be sold as they exist on the property at the time. This property can be sold without reclaim cost but the buyer will come and get that property as it stands. That is true of other properties shown in the exhibit where no cost of reclaim is set out. Page 20 shows the buildings that will be added after June 1, 1939.

Questions by the Examiner.

In certain places, I have used the percentages of value based on my judgment and on consultation with other witnesses. In other places, I have used a certain money value per unit of weight. The money value per unit of weight in determining gross revenue is a published fact and, in determining the cost of reclaim, it is in some cases my own judgment and in some cases I obtained it through consultation with others. Wherever I have used a percentage of value, or a monetary amount per unit of weight, and wherever I have used my own judgment or consulted with others, I have applied the results of those four factors to the quantity set forth in Exhibit 122 and, thus, have gotten the net salvage value as shown.

831 Information as to the production of natural gasoline under the price trend shown on Exhibit 119 is available in the statistics of the American Petroleum Institute.

The Texoma contracts with the two marketing agencies were arranged on a competitive bid basis; that is, the disposal of gasoline through Phillips Petroleum Company and Columbian Gasoline Company was on a competitive bid basis.

(At this point EXHIBIT 123 was offered and received in evidence without objection.)

832 **M. E. FOSTER**, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 29, 1939.)

My name is M. E. Foster. I live in Bartlesville, Oklahoma. I am employed by the Phillips Petroleum Company, an integrated oil company.

In connection with its business, my employer manufactures and handles a commodity known as natural gasoline. I imagine we are the largest single producer of natural gasoline in the industry. This fact, I believe, is recognized by the industry. I have been with the Phillips Petroleum Company approximately sixteen years. My first position was that of a chemist in one of the natural gasoline manufacturing plants. That work lasted for a year and a half or two years, when I was transferred to the sales department, selling natural gasoline to refiners; and then, as we went into the refining business ourselves, I grew into the job of sales manager in charge of tank car or wholesale sales of both natural gasoline and refined gasoline and also fuel oil and all other products that we sold at wholesale. I remained in that position until 1932, when I was transferred to the position I now have, which is coordinator. In my present position, I attempt to see that all the activities of the company dovetail and fit in together, to see that supplies of various raw materials that we work with are adequate and will be, planning ahead to assure adequate supplies. I work under the immediate direction of the president of the company, and my duties cover practically the entire scope of the company's activities including being interested in the purchase and handling of natural gasoline.

I do not negotiate all of the contracts, however. We have a man in one of the other departments charged with that responsibility, but in connection with assuring adequate supplies of natural gasoline, I am very much interested in the amount that we do buy and when we buy it, for what period we buy it, and I advise with him and recommend what we do and what we do not do.

I have kept up with the price tendency of natural gasoline during the period I have been with Phillips Petroleum Company. I am familiar with the history of that commodity and of the price trend. I am shown Exhibit No. 119 on which have been drawn two tracings or curves or charts, tracing by months the fluctuations in the price of natural gasoline and of what is termed as "United States motor fuel." I am familiar with the term "United States motor fuel" as well as natural gasoline.

"United States motor fuel" is a term adopted by the industry to designate motor gasoline normally sold for use in automobiles. The name was adopted from the recommendations of the government for the specifications on which the various government departments buy their motor fuel.

It appears from Exhibit 119 that during the years 1919,
1920, and for several years after that the price of natural
gasoline was substantially higher than the price of United
States motor fuel. That conforms with the facts as they
actually existed. Natural gasoline is not a motor fuel
as that term is ordinarily used. Its principal use is for
833 blending with gasoline made from crude oil to produce
motor fuel. It is one of the constituent elements often
entering into United States motor fuel. There were several
reasons why this raw product was worth more than the

motor fuel into which it was blended. Naturally, the amount of it that was available, the supply and demand, fixed the price, but I believe probably the best explanation would be that back in those earlier days, 1919 and along there to 1922 and 1923, the refiners found that by the use of proper fractionating equipment they could cut more deeply into the crude oil and still maintain the end point specifications as set out for United States motor gasoline and increase the yield of gasoline from a barrel of crude. By so doing, even though they did not get it too heavy on the back end, the average of the gasoline produced in that way was not volatile enough to burn satisfactorily in automobiles. They could, however, buy the natural gasoline and blend with it, and build up the volatility to the point where it would burn satisfactorily as a motor fuel. They could well afford to pay a premium rather than reduce the amount of yield from a barrel of crude. By utilizing it and paying a premium for it, they were able to get more United States motor fuel out of a barrel of crude.

That is not the situation today. Back in that period, the industry had not discovered octane number. The automobile engines were of relatively low compression and fuel made in that fashion was entirely satisfactory. As the automobile industry developed, they found that they could make more efficient engines by increasing the compression ratio, and the oil industry found that gasoline made in that fashion would not work satisfactorily in these higher compression engines, so they started improving the octane number by cracking and reforming parts of the crude oil, and in more recent years even by cracking what was originally the best gasoline, the straight-run gasoline, no longer sold in very large quantities. They even put such gasoline into what is known as the reforming still for the purpose of changing the chemical structure of this gasoline to where it would have a higher octane number. In this cracking and reforming process, the refiners produced not only a gasoline that had a higher knock rating but also a more volatile gasoline, so that they found that the natural gasoline was not so essential as it had been formerly.

However, they did not discontinue using natural gasoline altogether. Natural gasoline is still produced and still used. The only difference is that now the refiners tend to use it only when they are able to buy it at a price which will afford them a profit on the use of it. One way of putting it would be to say that the situation has changed from the days when natural gasoline brought a premium and the refiners had to have it, from what was then termed a sellers' market to what is commonly known as a buyers' market. There are other factors of course, depending on the supply of the material available and the demand for it. That fluctuates, and you can see those fluctuations there, in fluctuations in price, but the trend has been gradually downward. The circumstances that I have reviewed account for the gradual downward trend of the price of natural gasoline.

The chart shows the price for motor fuel in 1938 was lower than it was in 1937. Those prices would seem to be in somewhat constant relation there over the last four years; but the natural gasoline prices are considerably below the motor fuel prices, bearing out what I said a moment ago, that the refiners now will use the natural gasoline if they can buy it at a price at which they can make a
834 profit, but they are not obligated to purchase it, and
they can make their motor fuel without the natural gasoline. They buy it now as a commodity on an exchange basis and not as a necessity. That is true in general. You understand that there are all sorts of refineries. Some operate in one way and some in another, and there may be and probably are a number of refineries today which are still buying it as a matter of necessity. There are refineries operating without cracking plants today, although they are in the minority.

What I am endeavoring to do here is to outline the trend of the industry, the vast majority of the industry. The apparent fluctuation in the price beginning about the middle or the latter part of the summer and moving up until about the holiday season or the end of the year and then dropping, which seems to be characteristic of the annual behavior of natural gasoline prices, is brought about by the fact that the natural gasoline production is for practical purposes uniform throughout the year. These plants run day after day and produce roughly the same amount every day. The demand for it, though, is not uniform. The refiners prefer to buy their natural gasoline in the fall and winter months when they can blend it with their own production to better advantage.

One major value of natural gasoline is volatility, and volatility in motor fuel is highly desirable in the fall and winter months. So there is more demand during the fall and winter months than at any other time of the year. It is rather a perishable commodity and due to its vapor pressure, it requires special storage and rather expensive storage to store natural gasoline. As a result, very little of it is stored. It is produced and disposed of currently. That merely means that without the demand in the spring, the price reacts and goes down to where refiners will buy, then in the fall, without much reserve in storage, as the demand increases the price naturally reacts. Natural gasoline is a seasonal demand product.

Cross-Examination Interposed by Mr. Slaff.

The demand for motor fuel of course begins to fall off rather sharply in November and December. The seasonal demand for motor fuel, and the periods of the best demand for natural gasoline, while they vary for individual years, are September, October, and November. Those are the best months. You will find some years that the price carried through January in fairly good shape, in other years, it breaks off in November, depending again on the supply that is on hand and the demand, and largely on what the price of United States motor gasoline is at the same time.

Direct Examination Resumed by Mr. Morgan.

They are still using natural gasoline for such motor fuel as is being consumed during the winter months, but in less quantities because there are parts of the country that get so cold that automobiles are kept in the garage for a large part of the time. In other words, the percentage of natural gasoline used on through the winter months remains high, but the total volume is down. The production of natural gasoline does not vary seasonally as refinery production varies. So far as it is produced by natural gas companies it is a by-product, but so far as natural gasoline or casinghead gasoline plants are concerned, it is a main product with those plants. It is an incident to the production of crude oil and its production varies directly 835 with the production of crude oil. There would be substantially the same quantity of natural gasoline produced in the casinghead plants, depending on the volume of oil produced, and also from the natural gas which goes into pipelines and into carbon black, regardless of the season of the year. I concur in the view that there is a direct and definite relationship between the price of United States motor fuel and the price of natural gasoline. The relationship is likely to continue. It is particularly true with reference to maximum natural gasoline prices. The refiners have a tendency to discontinue the purchase of natural gasoline when the price increases to the point where it approaches the value of United States motor fuel.

I stated that Phillips Petroleum Company is the largest producer of natural gasoline in this country. Phillips handles other gasoline than that which it processes itself from casinghead gas and natural gas. We purchase a large quantity in Oklahoma and Texas, including the Panhandle.

It is the usual practice and custom of those handling natural gasoline to make a brokerage charge for the handling of the product. Where the sales agency handles the sales for the manufacturer, it is customary for him to make a brokerage or sales charge to cover his expense and profit of the business. In the purchase of gasoline for our own purposes, whether it be to blend with refinery gasoline at our own refinery or to re-sell, we endeavor to buy at a differential under the posted price.

Concerning brokerage or differential, each individual contract is subject to negotiation. It depends upon the salesmanship of the buyer and seller. All sorts of different bases are used in the industry. At the time I was actively engaged in the sale of natural gasoline, I would say that the average commission in those days ran about ¼ of a cent a gallon. While I have not been so closely associated with sales in recent years, I am inclined to think that the same type of brokerage commission is still customary practice. However, I am inclined to think that it is somewhat smaller than it was then—somewhat smaller than ¼ of a cent. Although I am not directly engaged in that at this time, it is my understanding that the sales commission would certainly average ½ of a cent.

To that the gasoline plant owner would have to add other charges that would come out of the total quantity of gasoline which he shipped to the refinery. It is customary trade practice for any outage or evaporation loss in the shipment to be charged back to the plant owner, for which, of course, he is not paid. He must also stand the freight on the outage which the customer has originally paid, but which he bills back to the producer. As natural gasoline is usually sold in North Texas or in Texas based on the Breckenridge freight rate to the Gulf, if the producer's plant is so located

that his rate to the destination is higher than the Breckenridge rate, he would have to stand the freight equalization in addition. Of course, his loading losses would be for his account, but that could hardly come in here, since we would start from the point where he loaded the gasoline in the
tank car. Therefore, there are the three charges—out-
836 age, freight on outage, and freight equalization—and
in my judgment, ⅛ of a cent brokerage charge prevailing at the present time.

Phillips Petroleum Company has a contract at this time with Texoma Natural Gas Company for the purchase of natural gasoline. I know about the circumstances under which that contract was negotiated, because it so happens that I was personally present in most of the negotiations of this contract. As to whether there was an allowance for brokerage in that particular instance can best be explained by stating the basis of the contract. We agreed to pay them the low market price as quoted in the trade paper, National Petroleum News. That was the renewal of the price under the former contract, or I might say, that is the customary sales price of the industry, and the only sort of commission or concession we were able to get out of this particular contract was the 2 per cent volume allowance for losses in handling. We pay them for 98 per cent of the gasoline gauged in their tanks. That contract runs until June 1, 1940.

I dealt with Mr. Davidson of the Texoma company in the renewal of that contract at its last expiration date. There were some side issues or considerations involved in the renewal of that contract. In order to secure the gasoline at the price stated, we were obliged to lease 100 tank cars at a rental of $25 a month per car for the period of the contract. That amounts to $30,000 a year. We did not want the tank cars. We wanted to put the gasoline into a pipeline system which connected to our plants and refineries, but in order to get the gasoline we had to take the tank cars, and we wanted the gasoline. It was necessary for us to take the tank cars in order to get the gasoline because there was an understanding or informal arrangement, as I understand it, between the Texoma company and the owner of the tank cars. We were told by Texoma at the time of the negotiations for the contract that such was the case. They said they had a moral obligation with this other company to sell them the gasoline. They stipulated the terms in the agreement as to the use of those cars. (Objection and motion to strike by Commission Counsel overruled and denied.) We wanted the gasoline. Texoma told us that they had a moral obligation to this other company, which had acquired these tank cars with the understanding that Texoma would sell them this output, and Texoma was in the embarrassing position, if they sold us, of not keeping their agreement with the other company. The other company was willing to give up that part of the gasoline which Phillips bought, which was one-half of the total production of Texoma's plant, only on condition that one-half of those tank cars would be taken off their hands on a rental basis. This involved a cost to Phillips Petroleum Company of $30,000 in addition to the market price less two per cent, which Phillips agreed to pay. It is my understanding that Phillips has no use for these cars. (Objection by Commission Counsel to above testimony overruled.) We were willing to pay this rental at a cost of $30,000 a year because we wanted the gasoline. We had certain sales commitments which, together with our regular demand, necessitated the purchase of additional natural gasoline in this particular area where it was needed, and we naturally bought the gasoline on the best basis we could buy it at the time.

We have other gasoline facilities and plants of our own in the same general vicinity as the Texoma plant. We also buy from others in the same area. We are not now in the same situation with reference to a need for this gasoline that we were at the time we renewed the contract and agreed to pay this premium and the market price with only the two per cent allowance for brokerage or
837 marketing expense of which I have testified. We have installed transportation facilities from Oklahoma City to our Kansas City refinery whereby we can move gasoline produced in Oklahoma to our Kansas City refinery as economically as we can move it from the Panhandle area where the Texoma plant is located. (Objection by Commission Counsel overruled.) I have been hopeful that this contract would be renewed but not on the same terms. As I have testified previously, this is rather a high price to pay for natural gasoline compared to the average price prevalent in the industry. We bought it at a time when we needed it and we paid for it. If the contract was up for renewal now, we would no longer be in that position, for we think we have now achieved the desired position. It is possible by next June, which is some distance away,

that circumstances will alter so that we might even be willing to renew the contract on a more favorable basis, but in my judgment, that is extremely unlikely. By "on a more favorable basis" I meant on a basis more favorable to Texoma.

Questions by the Examiner.

I am enabled to make that statement because it is my responsibility to follow the estimates made by various operating departments with reference to future production of natural gasoline, refinery gasoline, and, in connection with those estimates of supply, the estimates of our sales department as to what quantities they will require. We are constantly planning future activities in order to be sure that we will have ample supplies of the required quantities and qualities of gasoline at the proper time in order to meet our sales commitments. We were very reluctant to renew this contract this year before we had the new facilities which we now have. We make a monthly forecast covering the next twelve months period. The last forecast made, as of the first of August, would cover the period ending July 31, 1940. That forecast covers the quantities which we will produce balanced against our estimated sales. We estimate what we have already contracted to purchase. We have definite contract commitments from a number of manufacturers which we can count on definitely as a part of our supply. This Texoma gasoline is not treated as a commitment beyond the terms of this contract. We count in this calculation only that gasoline which is firmly contracted for.

Direct Examination Resumed by Mr. Morgan.

So far as we can see today, we will not require that gasoline on the present terms by the time that contract expires.

Cross-Examination by Mr. Booth.

The principal use for natural gasoline is in connection with blending motor fuel. It is also used in blending to make aviation gasoline, or it can be used solely as an aviation gasoline without blending if the lighter end of the material be removed by fractionation. There are some other minor uses. It is sometimes used to pump down in oil wells in an attempt to dissolve parafin accumulations. It is used rather unsafely as a cleansing fluid to take grease out of clothes, and it can be used in cigarette lighters. The principal use, as I say, is for blending to make motor fuel.

While Phillips may use the natural gasoline it buys, or sell it to others, the deduction it makes below the market price is commonly called a brokerage charge because it is a concession that the gasoline plant is willing to make to avoid the necessity of organizing and maintaining a sales organization. 838

Cross-Examination by Mr. Slaff.

I do not believe I have testified in any other cases on similar matters. I have never testified in any other lawsuits or rate cases.

839 W. D. SMITH, a witness for the defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 29, 1939.)

My name is W. D. Smith. I live in Tulsa, Oklahoma. I am engaged in several different businesses. I am vice president of the Worthington Machinery Corporation of Oklahoma, a sales agency primarily engaged in the selling of new machinery. This company has dealt also in the buying and selling of second-hand machinery. I am vice president of the Dumar Oil & Gas Company of Shamrock, Texas, which for years engaged in the production of natural gas. I am a partner in the Gasoline Plant Construction Company of Houston, Texas, which company is engaged in the construction and operation of natural gasoline plants. I am also part owner of a small company in the vicinity of Monument, New Mexico, which is engaged in the distribution of electric energy.

I am a graduate mechanical engineer but have never engaged in the practice of engineering as such. Since leaving the university, I have been employed by the companies already mentioned, except for a period from 1923 until the end of 1926, when I was employed by the Worthington Pump & Machinery Corporation of Buffalo, New York. I took a student engineering course in this plant and was later field test engineer for that company. I have never been employed by the Natural Gas Pipeline Company of America or Texoma Natural Gas Company. I have never been employed by the Standard Oil Company (New Jersey), or The Texas Company, or the Columbian Carbon Company, or the Cities Service Company.

There is no relationship between the Worthington Pump & Machinery Corporation of Buffalo and the Worthington Machinery Corporation of Oklahoma, except that the Worthington Machinery Corporation of Oklahoma is a sales agency operating in the state of Oklahoma for the sale of the products of the Worthington Pump & Machinery Corporation and of other machinery manufacturers—namely, the Hercules Motor Company of Canton, Ohio—and at times we have sold the products of other machinery manufacturers.

I am familiar with the equipment referred to here in the room yesterday and today as the Worthington compressor units. I am familiar with practically all of the machinery and equipment shown in Exhibit No. 122.

Since 1927, I have been engaged in the states of Oklahoma and Texas in the sale of new machinery and in the purchase and sale of used machinery. I helped organize a company—namely, the American Natural Gasoline Company at Shamrock, Texas—in the early part of 1934. This is in the Panhandle field near the town of Shamrock, in Wheeler County. I was one of the original organizers and was in complete charge of the building and operation of that plant for several years. The plant was shut down by order of the Railroad Commission of the State of Texas in February, 1936.

Early in the year 1937, I was instrumental in forming the corporation known as the Gasoline Plant Construction Corporation, which operated under the name of Western Supply Company for a time, although it had no connection with the Western Supply Company. This Gasoline Plant
Construction Corporation has built ten natural gaso-
840 line plants in Texas and Kansas during the past two
and one-half years. These have all been turnkey construction contracts and I estimate about one-half of the total plants in the Mid-Continent area have been built under turnkey contracts. These plants were built for the Humble Oil & Refining Company, Cabot Carbon Black

Company, The Natural Gasoline Corporation, Southern Minerals Corporation, the Hammond Exploration Company, and Agua Dulce Company. The Gasoline Plant Construction Corporation has charge of the operation of the Natural Gasoline Corporation plant at Aransas Pass, Texas.

Cross-Examination Interposed by Mr. Slaff.

A turnkey contract is a contract whereby we as contractors undertake to design, supply the material and build the plant and then turn it over to the operator. In other words, we start with a level piece of ground, where there is nothing on it, and finish with a gasoline plant ready to operate and turn it over to the owner. We have done work both on a cost-plus basis and on a stipulated price contract.

Direct Examination Resumed by Mr. Morgan.

I am familiar with the character and cost of material that enters into natural gasoline plants and with the building and operation of such plants. I have seen the natural gasoline plant of Texoma Natural Gas Company as recently as last Wednesday. I have known about that plant for several years, in fact since the time it was built, and I saw it on one other occasion about six years ago. I went through the plant last Wednesday, viewed the equipment and ascertained the type of equipment that is used in the operation of that plant, observed the buildings on the premises, their location, their cost, their size, and other things concerning them. I have also seen the Gray compressor station in the Oklahoma Panhandle near the town of Perryton, Texas, and the meter station and regulator station near Joliet, Illinois. I did not go to the other stations north of Gray, Oklahoma and on up to Geneseo, Illinois, as I was told that the other stations are practically identical to the Gray, Oklahoma, station. I examined the station last named to see what type of equipment was utilized there and looked at the buildings to ascertain their size, their location, and so on.

The experience of Worthington Machinery Corporation of Oklahoma, and I as an officer of it, has been very poor in buying and selling used machinery. We primarily are not engaged in the buying and selling of second-hand machinery. Most of our business is in the selling of new machinery, but in the selling of new machinery we are frequently confronted by prospective buyers with taking in second-hand machinery which they have on hand. Frequently, in order to sell new machinery, we have had second-hand machinery forced on us. In other cases, we have bought some second-hand machinery as such and have resold it. We have found it very difficult to sell this second-hand or used machinery.

From the standpoint of a project like these pipelines which have constructed gathering lines in the Texas Panhandle, gas wells scattered over the Panhandle field, compressor stations at intervals of 90 or 100 miles from the Texas Panhandle up to Geneseo, Illinois, and some 950 miles of pipeline of the larger dimensions, besides the smaller pipelines, the owners would have to place their equipment in the hands of dealers or sell it to dealers who are buying and selling that type of material every
841 day in order to dispose of it, as the Texoma or Natural Gas Pipeline Company are not familiar with the markets for such equipment and machinery. This handling of used machinery and equipment is a specialized field and requires the maintaining of an organization to keep up with where there might be demands for that kind of stuff. I doubt if those who have been operating the pipeline would be in a position to know where to sell to the ultimate user that type of equipment. If the equipment was of a character that it could not be sold as used equipment, it would have to be junked and sold to the junk dealer or transported to a scrap market.

This picture, marked Exhibit No. 123, is a picture of the Fritch compressor station containing 12—1250 horsepower horizontal twin tandem gas engine compressors. These engines are approximately 46 feet long, 24 feet wide, 9 feet 4 inches high. The larger elements of these engines are the power cylinders of which there are four weighing approximately 13,000 pounds each, the main crankshaft weighing approximately 20,000 pounds, the flywheel weighing approximately 25,000 pounds, and the main frame, of which there are two, weighing 42,000 pounds each. The parts I have mentioned are all cast iron with the exception of the crankshaft. The latter, the connecting rods, bearings, and piston rods are steel, and also other parts of a smaller nature.

I had nothing to do with the sale of these units to defendants. In fact, I have never sold either one of these companies any equipment or machinery. The demand for this type of equipment is in the main for trunk pipelines only. It is in very rare instances that engines of this size have been sold for any other purpose whatsoever. The manufacturing of these machines is very erratic. It is either a feast or a famine. There are years when Worthington has not built any machines at all of this size. In the case of the Panhandle gas field, they built a large number of units over a period of a very few years. My own experience while at Buffalo during the years 1923 to 1927 was that I do not recall their building a single engine of this size during that period. We have had no experience at all with buying and selling used machinery of this type. Until last night, I never heard of a single instance of such a transaction. However, Mr. Davidson informed me last night that there was a case where, when he worked for Cities Service Company, they bought three units from the Ohio Fuel Company and moved them some place from the East to the Mid-Continent. He told me, however, that these machines had only been used for a short period of time. There is only one other instance I know of where such machines have ever been taken off the foundations, dismantled and re-assembled in another location, and that was in the case of the Oklahoma Natural Gas Corporation where they moved several units from Shamrock, Oklahoma, to near Ballinger, Texas.

Being in the machinery business, we have calls all the time for various kinds of second-hand machinery. To my knowledge, my company has never had any call for engines as large as these Worthington compressor units, which were second-hand and twenty years old. These units are not stock equipment. The manufacturer builds them to special order. The engines owned by the defendants were built to special order and on special specifications. Assuming that these engines were 20 years old, I would say 842 that they would have no value at all and I would not give a dime for these 63 engines as far as re-assembling or dismantling them and moving them to a new location and putting them back in service again is concerned. (Objection by Commission's counsel overruled.) The only outlet would be to break them up and sell them for scrap. I have never known of a pipeline which has installed used equipment of this kind as a part of its operating machinery. There is no other use for this type of machinery. Occasionally the manufacturer of such machines has built power engines of the same size for driving either generators or pumps. However, the cost of taking these compressor units and converting them into power units would be so much, it would not be a commercial possibility. I recall that I sold 16 engines of this same general type of a smaller size, 700 horsepower, to the Phillips Petroleum Company sometime in 1930. They now have a number of these units which are not operating and which they have tried to salvage themselves for other purposes, and at each time they have gone through the calculations of taking these compressor units and rebuilding them into power units. The cost of doing this work was more than they could buy new power units for, so they let them stand and bought new ones.

Questions by the Examiner.

We are engaged in the sale of products manufactured by the Worthington Pump & Machinery Corporation, which corporation is not connected in any way with the Oklahoma company. That was new machinery we sold to the Phillips Company but was of the same general type as that used by Texoma. The products of Worthington Pump & Machinery Corporation vary from engines of this type here, condenser engines, air compressors, gas compressors, motor driven, steam driven, centrifugal pumps, direct acting steam pumps, condensers, water feeders, a general line of machinery. I have handled that line personally in the state of Oklahoma and have actually sold machinery of all of those types. The sales of machinery in Oklahoma are naturally in large part to the oil companies and pipeline companies, including all branches of the oil and gas industry.

Direct Examination Resumed by Mr. Morgan.

I am familiar with the equipment referred to as PIW and AOS scrubbers which belong to defendants. I have seen these scrubbers at Fritch, Gray, and Joliet. I have also seen the Blaw-Knox scrubbers. I know of no salvage value for these scrubbers except as junk. They are especially built to remove the dust from the natural gas going through the pipeline and are highly specialized equipment and I know of no other place where they could be used as such. The same is true of the 98 horsepower Casey Hedges water tube boilers, and equipment of that kind, belonging to these companies. The cost of tearing down the brick settings and moving to a new location would greatly exceed the cost of new boilers of that style and size.

I have sold lots of equipment of the type listed under Account No. 1006-E, including engines, generators, and so forth, and including the Cooper-Bessemer 175 kw. generators, the 25 horsepower motors for air compressors, and the other equipment listed on page 25 of Exhibit No. 122. It is possible that defendants could sell equipment of this type. However, bearing in mind that it will be 20 years old when it is salvaged, or when that pipeline is shut
843 down, it means that this equipment will have to be sold to a dealer. The dealer in buying it would have to remove it from its location, take it off its concrete foundations, load it on cars, and move it to his warehouse. There is not a ready market for the number of generating units listed in this account. The dealer, therefore, would have to hold them a number of years, in all probability, before he could sell them and would have to recondition the engines and generators before he could make a sale. Ordinarily a plant of this character would cost approximately $100 per kilowatt, including the foundations, the building, the generator and accessory equipment, and I feel that machines of this age would not have a salvage value of over $5 per kilowatt. It is very doubtful if a dealer in buying such a plant, would realize anything from the engines themselves. His salvage would be more on the electric equipment than it would be on the gas engines.

It is necessary to recondition that equipment, even though it was used right up to the time the pipeline ceased to do business. A dealer could not afford to take any chance with the condition of these engines. In order to satisfy himself in his relationship with a prospective customer, he would have to protect himself and tear the engines down and rebuild them, do whatever work was necessary. After he had moved this type of machinery from its location on the properties of these pipelines, paid the hauling, the freight and handling charges and costs, the reconditioning cost, and things of that kind, he might over a course of years be able to sell equipment of this age at a price not to exceed $20 per kilowatt. During the time that he would have to keep it after reconditioning, he would have the expense of warehousing and paying taxes on the equipment. In this connection I might point out an example of a similar power plant which we purchased five or six years ago from the Carter Oil Company. This plant had three gas engine driven generating units approximately 125 kw. each. We paid $10,000 for this plant complete, including the buildings and water pumps, cooling towers, cooling coils, and everything else, and the switchboard in that plant. We reconditioned the engines but, due to their size, we did not feel like moving them from their location 100 miles from our warehouse, so we kept a watchman on the ground approximately three years. Then we finally sold this plant for $14,500 and considered ourselves very lucky to get out of the deal.

You might check back to the price per kw. We paid a greater price per kw. than is indicated here due to the fact that these were only four years old when we bought them, but even so it shows that it is very difficult to sell second-hand machinery of this type. There are very few companies that would buy it. None of the major oil companies themselves would consider the installation of second-hand equipment of this type, so we have got to go to the smaller, hardly able oil companies in order to sell it. By "hardly able oil companies" I mean companies operating on a shoestring with limited financial resources. This sort of transaction usually means that with equipment of this type, considering the type of companies you have to sell it to, you are taking a credit risk when you are finally able to make a sale, and at that time you usually have to put up with additional terms on it.

844 There are a large number of electric motors on page 25 and appearing elsewhere in this exhibit. Treating these motors as such, I feel that the salvage value of 10 per cent allowed is very high. This takes into consideration no reclaim value. The dealer would pay 10 per cent for motors which are 20 years old at their present location and then have to move them from their foundations, load them on cars, transport them to his warehouse, recondition them in some cases where the insulation would be gone, and take a chance on being able to realize not over 20 to 25 per cent of the new price of the motors after he has gone through this work. I feel, therefore, that a value of 10 per cent is more than a company could afford

to pay for such motors. The same thing would apply to all motors in this exhibit.

Referring to the item "Machine Shop Equipment" costing $24,824.43, which is given a listing of 15 per cent of cost, I know what machine shop equipment is. It consists in general of small tools, small lathes and drill presses, grinders, etc., which at times have a ready market, and I feel that a value of 15 per cent for such equipment is adequately high; that is, at its present location.

Referring to the tanks, I am familiar with that type of equipment. In general, tankage 20 years old has no value except as junk. However, I have allowed a price of 5 per cent of the original cost at its present location, which I feel is more than most dealers would give for such equipment. That applies to all tanks, except those which are too large to haul. On page 27, there are some nine 100,000-gallon elevated tanks which are immense structures and which could not be moved to a new location. They are riveted tanks. The smaller tanks, as a general rule, can be moved without tearing them down; but a large tank like a 100,000-gallon tank or a 200,000-gallon tank which has been riveted there on the ground—that is, the sheets are held together by rivets applied after the material composing the tank has been put on the ground—cannot be so moved. The only practical method of cutting down a tank of that character is to use acetylene cutting torches. It is impractical to go there and take a chisel and knock the heads of those rivets and get them out that way.

There are a large number of buildings at the Fritch plant and also a number of buildings at the Gray plant. These are structural steel buildings. The framework, trusses, and all parts are made of steel and the walls and the roof of the main compressor buildings are covered with transite, a fabricated material. The only way to dispose of buildings of that sort in large numbers is to sell them to dealers in this type of equipment. There are dealers who make it a business to go out and acquire buildings of that kind, dismantle them and then resell them. Referring to the smaller buildings, the auxiliary buildings, warehouses, garages and buildings of that type, I believe they could be salvaged for 10 per cent of their original cost on the foundations where they now are. I mean 10 per cent of the cost of the movable material. I base this on a general knowledge of buildings of this type in the Mid-Continent field, the going price of such buildings. These smaller buildings could be resold by a dealer to operators of natural gasoline plants; while such operators would not consider the use of second-hand machinery, they would feel that they are taking no risk in installing second-hand buildings.

845 The larger buildings, such as those which house these main compressor units and those other large buildings that I saw out there on those sites, could not be handled in this manner. There is no use for buildings of this size in the oil industry except for main gas line compressor station buildings. They would, therefore, have to be refabricated by a dealer into smaller sized buildings, and the dealer would not pay the percentage for the larger buildings that he would for the smaller ones. In all dimensions, these buildings are too large for rehandling and reassembling for ordinary commercial purposes. By "refabricating" I mean that the dealer would have to completely dismantle these buildings, move them to a shop and cut the various parts of the building into smaller sizes and then re-erect them at some new location as smaller buildings. That additional expense would cause the dealer to pay a smaller price for the larger buildings than he would for the smaller buildings. Ten per cent would be my judgment as to the small buildings and 5 per cent for the large buildings.

On page 25 of this exhibit is listed at the bottom of the page "18 C. P. Air Compressors" and "36 Dayton Dowd Centrifugal Pumps"; also, certain steam pumps, duplex pumps, and equipment of that character. This type of equipment can be overhauled and resold. However, it is my experience and the experience of others buying second-hand air compressors of this small size, centrifugal and direct-acting steam pumps, that if we were given this type of equipment free, considering its age, we could not replace the defective parts and pay the expense of hauling it from its location to our warehouse, and pay the machine shop charges and labor required to do the work, and sell it in competition with new pumps. I have had this experience in buying a large number of pumps of all sizes and types, and as a general thing it is impossible for us to recondition these pumps even though they are on our books at no cost. We have a warehouse full of them in Tulsa. We will sell them for scrap eventually. I might further add that on centrifugal pumps and direct-acting steam pumps, the cost of replacing parts greatly exceeds the cost of the complete new pump. If you would have to buy a complete set of working parts for a pump, the cost of these parts alone exceeds the cost of the complete new pump.

I am familiar with the type of equipment known as transformers, listed on pages 30, 31, 65, 66 and 77, under Account No. 1006-I, as "Electrical Material (Exclusive of Motors)". I have sold new transformers and have purchased some second-hand transformers. These transformers will have to be sold to dealers engaged in the buying and selling of second-hand electrical equipment. Considering the fact that they will be approximately 20 years old, a dealer would not pay over 5 per cent of the original cost at their present location. That is true of all similar types of equipment; that is, similar equipment of that type listed on the various pages above enumerated.

I have studied the list of equipment shown on pages 32, 33, 67, 78 and 79 of this same Exhibit No. 122 under Account No. 1006-J, "Miscellaneous Equipment", consisting of a large number of items. I am familiar with the types of equipment that are listed under this caption with the possible exception of one or two items. I know of no dealer who handles such a wide variety of equipment as is
846 shown on those pages. It seems to me that if a dealer could be found who would buy all this wide variety of material, he would not be willing to pay much of a price for it. There are very few companies that would consider buying second-hand material of this type and the price that I have given of 10 per cent of its original cost is, in my estimation, a high percentage to allow for equipment of this age.

On page 32 are shown 6 Maihak engine indicators which cost $1,056. I own one of these indicators myself and have it in Tulsa. I have had no use for it for the last 13 or 14 years and at various times have tried to sell it for as little as $25 without success. Due to the fact that it is 12 or 13 years old, there is no buyer for such type of equipment. The equipment listed on page 68 should be included in that covered by the observations I have made concerning that listed on pages 32, etc.

I have studied the list of material under the heading "Meters and Regulators", Account 1009, shown on pages 35, 36, 37 and 82 of the same exhibit. I am familiar with that type of equipment. These meters are all of a type that are not only used in gas pipe work, but they are used as field meters in the measurement of natural gas going to gasoline plants, and there is some market for such meters, although the larger oil companies would not consider their use. As an operator of gasoline plants, I would not install second-hand meters myself, due to the fact that I would not want to get into any squabble with the royalty owners over gas measurement, which would certainly follow if second-hand meters were installed. However, there are some companies which do move their meters around and buy second-hand meters. The price that I have allowed here of $25 a meter is the present market price of second-hand meters after they have been reconditioned and put in salable condition.

On page 35 and other pages listing the meters, I have used a price for the large meters of $25 and a lesser price for the smaller meters. It was my offhand guess that the regulators and governors shown on pages 36 and 37 would be worth 10 per cent of their original cost. This was before I visited the Joliet regulator station. After considering this matter further and visiting the site of the installation, I do not feel that these regulators would have any value as second-hand equipment. Such a type of equipment as this is very special and there is a very limited second-hand market for such equipment. Also, there have been many improvements on regulators of this type, and regulators 20 years old are, as a general thing, obsolete. It is now my judgment that those regulators at 20 years of age would have no value except as junk.

I have gone over and studied the list of miscellaneous equipment under the caption "Tools", Account 1013, appearing on pages 43 to 47, inclusive, and on pages 87, 88 and 89 of this exhibit. I have seen much of this equipment in the Fritch and Gray stations. I have indicated a 10 per cent salvage price on this equipment, which I feel is more than ample to allow for equipment of this type, since the same objections apply to this equipment as to that on the previous page, in that it could not be sold to one dealer except at a sacrifice in price. In other words, there is such a wide range of equipment listed on those pages that no one dealer could be handling all of it.

847 The equipment listed under the caption "Wood Frame Buildings" appearing on several pages of the exhibit—namely, pages 21, 56 and 84—consisting of 4-room cottages, 5-room cottages, duplex cottages, bunk houses, 5-room boarding houses, and office buildings, is listed at

$100 apiece. I have seen the houses at the Fritch and Gray stations. I am not a dealer in real estate and have never bought or sold any houses. However, my observation regarding these houses is that they are of the same general type of oil field cottage, of which there are thousands in the Texas Panhandle, which have been built since the discovery of oil and gas in this area. In time this oil field will be exhausted and there will not only be these houses for sale, but there will be thousands of other similar houses for sale. The population will dwindle to practically nothing, the same as it was before oil and gas were discovered in this area, which is what is commonly known as the "dust bowl" of the Texas Panhandle, Oklahoma Panhandle, and western Kansas. The population, outside of the people engaged in the oil and gas business, is practically nil and is confined to those engaged in ranching and dry farming. Instead of having a salvage of $100, it would be my judgment that the company would have to stand the expense of tearing these houses down and getting rid of them, due to the fact that there will be thousands of them available at such time. I had nothing to do with the salvage value placed on those items, but I am stating my judgment about it.

The figures about which I have been testifying, dealing with the salvage values of machinery, steel buildings, and things of that kind, are largely mine. (Motion by Commission Counsel to strike testimony with respect to estimates of salvage value which have been prepared by somebody else denied.)

My testimony concerning the salvage value of the wooden frame buildings is confined to those located in the dust bowl area above mentioned. I would have no judgment at all as to what these buildings would be worth on the north end of the line. I have no knowledge of conditions there.

I have lived in the Texas Panhandle for 2½ years and I am familiar with conditions in that area. I am familiar with the equipment shown on page 22 under Account No. 1006-C, captioned "Water Well Equipment", and on page 23 is a list of equipment of the same kind to be added hereafter. As regarding the motors, the same percentage is applied here as has been applied elsewhere in the exhibit; namely, 10 per cent of the original cost at its present location. Somehow or other a price of 10 per cent was allowed on the vertical deep well pumps. I do not know how that got into the exhibit as, in my opinion, these pumps are worthless except as junk. Vertical deep well centrifugal pumps are designed to handle a given volume of water at a certain depth through a certain sized casing and it is very doubtful whether pumps which are so special, and which have such special characteristics, could be moved to other water wells where they would be required to handle a different volume of water under different operating conditions. These pumps are operating in wells containing a certain amount of sand and at the time they are pulled for reclaim they require practically all new running parts. It would be my judgment that these pumps should be left in the wells where they now are rather than to try to salvage them for any purpose. We have been offered this type of equipment a number of times but have never purchased a vertical deep well centrifugal pump second-hand for the reasons above stated. I know of no dealer who would buy a second-hand deep well pump of this type.

848 I am familiar with the type of equipment listed on page 70, Account 1007-B, C, D, "Loading Rack, Siding and Absorbers". I see listed here an 8-car double loading rack, 265,198 pounds of railroad siding, totaling 132.6 tons, and 9 absorbers with controls. The first item, the 8-car double loading rack, is a fabricated steel rack, folded together, and has some market value. It is an item which an oil company would not object to installing second-hand because it is assumed that the steel is in good condition and could be torn down and moved to a new location. However, a double loading rack is less prevalent than single car loading racks. It is only in the larger gasoline plants, such as this, which manufacture daily a large amount of gasoline, that they require a double-car loading rack. For the average size natural gasoline plant which has about half the production of this Texoma plant, they would need a smaller loading rack. However, it can be broken down and shipped to a new location and sold. Considering its age, I have allowed a value of 10 per cent on this item. That is my judgment as to its value.

The absorbers are a questionable item. They are designed for high working pressure and are especially built to meet the needs of this gas pipeline. However, there are natural gasoline plants operating along the Gulf Coast which would use absorbers of this high pressure and this size and I have allowed a value of $1,000 per absorber, including the small controls that are on those vessels, as a reasonable going price for such an item of equipment. I certainly feel that they would not get more than that for those absorbers.

I have had only one experience with railroad siding. That was in the case of the gasoline plant that we built at Shamrock, Texas, where we constructed a spur track on the Rock Island right-of-way. When we shut the plant down and abandoned it, we gave the spur track to the Rock Island Railroad, as we did not feel that we were justified in the expense of salvaging the equipment thereon. In other words, we felt it would cost more to salvage it than we would have been able to sell the material for as salvage.

I think I have testified on the general character of equipment listed on page 71, Account No. 1007-E, consisting of pumps, motors and engines, with the exception of the Clark gas engine driven compressors. These are small machines, smaller than the main line units, and are used in the gasoline plant at Fritch. At the present time, the market price for engines of this size which are not over 7 or 8 years old is $2,500 each, after they have been thoroughly reconditioned by a dealer engaged in the buying and selling of second-hand machines. I have allowed a value of 5 per cent of the original cost for such machines at their present location. It must be borne in mind that these engines will have to be taken off the concrete foundations, moved to the railroad, and then moved to the dealer's warehouse where he would have to recondition them and make sure they were in salable condition before he eventually made a sale. I feel that 5 per cent is ample for these items. I am not talking about these items that are going to be junked, but only of those which show no cost of reclaim and which are dealt with as salvageable equip-
ment which can be sold on the ground to dealers for
849 resale. Those are the items which have percentages
opposite them instead of per ton prices. I am not in the business of buying and selling junk, so the prices where they are given on a per ton basis, I have had nothing to do with at all.

That brings us to the "Miscellaneous Equipment—Gasoline Plant," Account No. 1007-J, shown on pages 78 and

79. This is the same general classification of material as that covered on page 32 about which I have testified. All that I have said concerning the material listed on pages 32, 33, 67 and 68 applies to all of this gasoline plant equipment listed on pages 78 and 79. I cannot conceive of anyone who has a knowledge of the machinery business allowing a higher figure than I have indicated and set out in Exhibit No. 122 for machinery and other types of equipment and materials with which I have dealt in my testimony. In my judgment, these figures represent the fair and reasonable salvage values of that equipment if it was offered for sale at present prices, assuming that it would have the age and use that it will have had by the end of 1954.

In connection with my operating a natural gasoline plant in the Panhandle for a couple of years and with my firm's operating a plant at Aransas Pass, as above stated, I have had occasion to market gasoline. We did not maintain a sales organization but have sold it to brokers in that business. The principal buyers of natural gasoline in the state of Texas are the refineries who are the ultimate purchasers. I have mentioned how it is handled through brokers, who in turn sell it to the refiners. At Shamrock, Texas, we sold our gasoline to the Warren Petroleum Company, with whom we contracted the entire output. We paid them a commission of 3/16 of a cent a gallon when the posted price was below 3 cents a gallon and ¼ of a cent a gallon when the posted price was 3 cents and above.

At Aransas Pass, we are also selling our gasoline to Warren Petroleum Company and paying them a flat quarter of a cent a gallon as brokers. The brokers' commission does not include the outage, the freight on the outage, or the freight equalization. These items are paid by the owners of the gasoline plant. So far as I know, all gasoline plants with very few exceptions pay a brokerage for the sale of their products. We have our ideas as to the future price of natural gasoline. For the past 5 years I have spent most of my time in the building and operation of natural gasoline plants. We are frequently called on by people who do not own or operate gasoline plants but who have natural gas available. They call on us to make estimates as to the cost of building and operating these plants and ask us our advice as to the pay-out of such plants. For the past three or four years, we have consistently used a price of 2-½ cents per gallon net at the gasoline plant for grade 26-70 natural gasoline, and it is our judgment that the price in the immediate future will not vary very much from this. My judgment is in line with that of the other witnesses who have testified that there is a definite relationship between the price of natural gasoline and the price of United States motor fuel. There is no substantial outlet for natural gasoline except to oil refiners.

I am familiar with the type of equipment listed in Account No. 1006-G and shown on pages 28, 62 and 75 of Exhibit No. 122, in which are listed material called 850 Bentube cooling sections, size C-169, and also other sizes. These cooling sections are all of the same general type and are used for gas, water and oil cooling. These Bentube sections are installed in the bottom of the cooling tower and either gas, water or oil passes through the tubes and the cooling water from the top of the tower falls on these sections and cools the medium passing through the tube. These sections are used universally in all gasoline plants. I am assuming that at the time this plant is shut down, these sections will be in workable condition and as such, I have given them a value of 5 per cent of their original cost at their present location. The dealer buying these sections would have to remove them from the cooling tower, load them on trucks and haul them to the railroad and store them someplace in his own warehouses until he has a sale for them. He might also have to replace a number of defective tubes which are of admiralty metal. The gas coils are built for high pressure and have a very limited demand.

The fact that this salvage equipment runs into sizeable numbers of particular units or a very large quantity in terms of pounds or tons makes it more difficult to dispose of it. In a number of instances in this exhibit, it is conceivable that a buyer would pay slightly more than the percentages indicated here, if buying one or two items of the type. In order to dispose of this material piece by piece, it would be necessary for defendants to go into the selling end. A buyer purchasing it all has to consider the quantity that is available and, although he might pay a slightly higher percentage for one or two items, I consider the prices indicated here are very high, considering the vast amount that is going to be available on the market.

The type of equipment in Account No. 1013, "Tools," listed on pages 43 to 47, inclusive, and on pages 87, 88 and 89, was probably acquired by these pipelines one unit at a time, and in selling it out a dealer would have to sell it one piece at a time, or at the most just a few pieces at a time. I do not think a dealer buying all of this equipment would ever sell it all. I think the dealer would finally have to junk part of it. That is illustrative of other items shown in the inventory, especially in the case of laboratory equipment and special apparatus, thermometers and pressure gauges and equipment that is peculiar to this type of pipeline only.

The equipment called "Compressor Station Engine Parts" and "Warehouse Stocks" listed on pages 94 and 99, consists principally of the Worthington compressor parts. Assuming that the gas in the Panhandle is going to be gone, there are not only the engines involved on this one pipeline, some 60 engines, but there are half a dozen other pipelines going out of this same field. Therefore, all of these engines would be shut down and there would be no demand at all for repair parts, so that the manufacturer would not take them back even if they were new and unused, for no dealer would buy them as the engines would all be shut down. They would have to be junked and sold as ordinary scrap.

Cross-Examination by Mr. Booth.

I base my judgment as to the salvage value of the machinery and equipment on the fact that it would be about 20 years old at the time it is offered for sale. That was true as to all the equipment and machinery. The amounts stated are based on prices prevailing as of June 1, 1939. However, the valuation that I have made on most of the items is on a percentage basis rather than on a dollar basis.

It is stated as a percentage of the original cost. I should
851 not say original cost, I should say the present day
cost as of June 1. I did not obtain the figures shown under the caption "Original Cost Per Unit" on page 87. They were supplied by Texoma Natural Gas Company from their books. I merely estimated the percentage of the original cost that these items would bring if they had been in service for a period of 15 or 20 years. My estimates were based on the original cost which was intended to refer to prices as of June 1, 1939. I only estimated the percentage of value. It is my understanding that the prices shown on the exhibit were the prices originally paid for the material. There might be some difference between the prices in-

dicated and the prices as of the present day. What I did here was to price the salvage in terms of a percentage of the original cost in the light of present day salvage values. I related the present salvage values to the original cost and stated it in terms of percentages. (Motion to strike by Counsel for the Illinois Commerce Commission overruled.)

Cross-Examination by Mr. Slaff.

I intended to apply these percentages to the original cost of the material as paid by these pipelines, assuming that it is of an age of 20 years or thereabouts. The reason I applied those percentages to original cost rather than to present day cost of the same material or the same equipment is that the only information available is the prices that were paid by these companies for this material, and if they were applying those percentages to the present day costs they would necessarily have to go out and get quotations. I did not inquire if the company is preparing a reproduction cost estimate. Some of this material, as far as today's market, may be of higher price, and some of it may be of lower price.

Redirect Examination by Mr. Morgan.

(August 30, 1939.)

The only prices that I had available in estimating future salvage value were the cost prices that these pipelines paid for this material, and I applied a percentage, based on my judgment as of today, to these cost prices. However, this exhibit contains two bases of prices; namely, the original cost of the material installed before June 1, 1939, and prices as of June 1, 1939, for material that will be installed after June 1, 1939. There are very few items on which I have testified that will be installed on this pipeline after June 1, 1939. The bulk of the equipment, the main machinery, is already in place and the future machinery to be installed is a very small percentage of the total. I recognize that some of this material at the time the pipeline is salvaged will be from a few years old up to 10 or 15 years old. However, the main bulk of the machinery will be approximately 20 years old, and any dealer buying all of the equipment would not go through the stations and pick out and recognize just a few items which were 5 or 10 years old instead of 20 years old, because, as I say, the main bulk of the machinery will be approximately 20 years old. In other words, a dealer dealing with the whole mass of material concerning which I have testified would treat the entire material on a lump-sum basis.

Coming back to the Worthington engines, concerning which I testified yesterday, I have since I left the stand yesterday afternoon obtained some information from the general office, for which I had been looking prior to testifying yesterday, as to the number of these engines that have been manufactured and sold in the past. I have here a list received from the Worthington Pump and Machinery Corporation of Buffalo, New York, of all the engines of this size sold since the year 1913. That organization has manufactured at least half of all of that type of large engine units sold since that year. During that 26 years, they have manufactured 250 of these big engines. All except four of them were sold to natural gas pipeline companies. Approximately ¼ of all of them belong to defendants, who own 63.

852 *Cross-Examination by Mr. Booth.*

I determined the salvage value of the meters and regulators shown on page 35 of Exhibit No. 122. I do not know the dates when all of these meters were installed. I have assumed that most of them were installed when the pipeline was built. I did not go over every meter in the system. However, in that connection, I have given a value of $25 to these meters and even though these meters were installed as late as one year ago, I still would feel that that was a fair value for these meters. That in my opinion is a high value.

I determined the salvage value of the transformers but not of the copper wire shown on page 30 of this exhibit. The salvage value was arrived at on the basis of a percentage of the original cost. My understanding of the original cost figures used throughout this exhibit, is that they were for material only and not for any labor involved in setting the equipment up. The prices are those paid by the pipeline companies at the time they purchased the material, ranging back approximately 7 or 8 years ago. I do not have the exact dates when these various pieces of equipment were purchased. It is my understanding that these are the original costs and I am considering all of this equipment as being of an age of approximately 20 years.

The figure $75.50 shown under the caption "Net Salvage" for nine 25 K. V. A. transformers, represents 5 per cent of the original cost. It represents the price a dealer would pay for equipment approximately 20 years old in the light of present-day market for such equipment. Used machinery is bought on the basis of its original cost. The buyer considers the original cost and the seller has in mind what he has paid for such material, and if the cost figures vary, for example if these transformers were bought in 1931 and they have increased in price until today, I have applied a percentage of 5 per cent to the original cost. If I were using the price of today, I would apply a lesser percentage. The percentages I have used in connection with this exhibit are all based on the original cost figures.

In figuring these percentages, I have based them on my judgment of the market as of today and have applied them to the original cost price. That is the way second-hand machinery is sold, on the basis of its original cost. The consideration that the purchaser would give to present-day prices of similar new equipment is reflected in my percentage basis. In the case of a transformer which in 1919 cost $2,000 and which, as you state, in 1939 cost $100, I would not apply the same percentage I have applied here, but would apply a zero percentage. The prices used are the original costs and the percentages arrived at according to my knowledge of present-day values and markets.

The prices used in the exhibit are the prices that the companies paid for the material, but in estimating the percentages applied to these costs, I have used the percentages based on the market for such machinery today. In other words, Mr. Booth has drawn a hypothetical example and my percentage instead of being 5 or 10 per cent on such an item—he mentioned transformers which I have given 5 per cent—it would have no percentage value at all in the light of present-day markets.

853 *Questions by the Examiner.*

In fixing my net salvage value, I used original cost, which is the cost price paid by the company, but in estimating the percentage, I had in mind the present-day market for used machinery.

Cross-Examination Resumed by Mr. Booth.

I have used an arbitrary or definite percentage in practically all cases of 5 or 10 per cent, because it was my opinion that the purchaser of the old equipment would pay 5 per cent of the original cost of the equipment if it was approximately 20 years old.

Assuming that 9-25 KVA transformers were purchased in 1930 by the Natural Gas Pipeline Company for $1,510, I have arrived at a salvage value in the amount of $75.50, by taking 5 percent of the original cost. Assuming that in 1950, when the equipment is 20 years old, the cost new of similar equipment instead of being $1,510, is $15,010, a prospective purchaser would pay 5 percent of the $1,510.

If you assume, as you state, that the transformers cost the company $1,510 in 1930 and could be purchased new in 1954 for $150, the percentages would have to be varied then in the light of markets in 1954. I have based my percentages in the light of the market as it exists today and that percentage is related to the original cost, but the basis of the percentage is in the light of what the market is today for second-hand machinery.

Cross-Examination by Mr. Slaff.

When we go to buy a second-hand transformer, we determine the price that was paid at the time it was purchased, say 10 years ago. The seller has in mind the price that he has paid for the equipment; in every instance, when I am buying second-hand material, I first make an investigation to determine what the original cost of that material was in the year in which it was purchased by the seller; in machinery of this kind it is all tagged with serial numbers, and it is very simple to go to the manufacturers and get the specifications and the year in which it was manufactured. Most of the material of the nature in this exhibit is owned by the major oil companies and gas pipeline companies. They have very complete records of their material and specifications upon which they purchased it, and we can usually get their purchase orders and check the specifications and prices. So in that case we do not feel that it is necessary to go back to the manufacturer and find out what this company has purchased in the first place. However, this material sometimes moves around and some other company may have acquired it and maybe that company would not have the complete record. In that case, we would go back to the manufacturer and find out just what we were buying.

This material is of such a special nature that the average person looking at it cannot tell the specifications and how it was built in the first place, and we want to know what we are buying. So in order to determine the original cost, we go either to the books of the seller and take the original cost from the books, or else to the manufacturer and get the cost to the seller from the manufacturer. It is not necessary in all cases to go through that procedure. We know in the case of some of this material what the market is and what the net prices for this second-hand material are, regardless of going through the original cost and applying the percentages as related to present-day markets. We know the market, at least we think we do, for machinery of all ages. The market is based on the original cost, allowing for conditions as they exist at the time. There is a wide variation in cost, say, in two different years. For example, there was a wide variation in general price levels in 1920 and 1921, or in 1921 and 1922. Prices went up to a great peak point after the war and then dropped sharply. If there is a wide difference in original cost of equipment purchased in 1921 and equipment purchased in 1922 of exactly the same type, the same wide variation of cost is carried into the second-hand market for that material or equipment in 1939.

854 *Redirect Examination by Mr. Morgan.*

By my last statement, I meant that when one of these sellers has a lot of material of this kind to sell, he makes a list of it before going to seek a buyer and attaches to that list invariably what it cost him, so the buyer has the figures of original cost when the seller gets to him in the first instance. As a rule, the material list is so marked and in the event it is not marked, we ask the seller what he paid for it. We fix the percentages in the light of the present-day conditions or the present market for used material. There is a relationsihp between the market for new material of the same kind and the price the dealer in used material will pay for it as used material. That is what I mean when I say I take into account the marketing conditions as at the present time. When we take these into account, regardless of whether the seller bought in 1921 or 1922, we apply the percentage to what he paid for it that the present market justifies, and that is what I meant by saying that it is based on the original cost as a practical proposition.

Cross-Examination by Mr. Slaff.

The price we can get for used material today determines what we will pay for it, and the price that the purchaser will pay us for it depends, as far as he is concerned, on the relationship between the value of second-hand material and equipment and new material and equipment.

Redirect Examination by Mr. Morgan.

With the percentages stated in the exhibit, 5 or 10 or 15 per cent, I have used all three of these percentages, I have taken into account that very relationship about which Mr. Slaff was speaking. As of today, I feel that those percentages are proper percentages to apply. They might not have been the same percentages three years ago or they might not be the same in 1954.

855 G. M. DAVIDSON, recalled for defendants, testified as follows:

Direct Examination by Mr. Hedrick.

(August 30, 1939.)

In order to straighten out the record and make it perfectly clear where the prices shown in Exhibit No. 122 for materials purchased prior to June 1, 1931, were obtained, I wish to explain that they were taken from the books of the company. As to the materials which have been purchased or are to be purchased after June 1, 1939, where prices are shown for them, I secured these prices from the exhibits submitted by Mr. Strong, Mr. W. H. Davidson, Mr. Powers, Mr. Bulla, Mr. Campbell, Mr. Bussard, Mr. Dickinson and myself.

On pages 13, 15 and 54 of this exhibit there are certain items where the words "Not Salvageable" as on page 13, and "No Salvage" as on pages 15, 53 and 54 appear. There are other items of property of both defendants which are not shown at all in this exhibit and which are not salvageable, according to information from other witnesses who will follow me on the witness stand and testify concerning those items. In the light of this information and of my own experience, it is my judgment that the items not listed are not salvageable. I have prepared a list by account number classifications, such as 1002, etc., showing additional non-salvageable property of the two companies. When this list of non-salvageable property goes into the record, it and Exhibit No. 122 and that property concerning which I have already testified as being non-salvageable, will include all of the property now owned by these two companies and all that will be added thereto which will be on hand as of the end of 1954. Of course, in addition to these properties there are the gas leases of Texoma which will automatically expire when there is no further production. We have no fee interest in these leases. They are somewhat like the right-of-way easements, in that when the use ceases the right in the property ceases as I understand it.

(At this point the witness produced certain lists of property entitled "Natural Gas Pipeline Company of America—Non-salvageable Property Not Listed in Exhibit No. 122" and "Texoma Natural Gas Company, Non-salvageable Property Not Listed in Exhibit No. 122." The Examiner thereupon instructed the reporter to set forth in the record the items contained in such lists as follows:

856 Natural Gas Pipeline Company of America

Non-Salvageable Property Not Listed in Exhibit #122

Account Number	Description
1002	Telephone System Right-of-way Easements.
	Various Land Easements at Stations for Drainage, etc.
1005	Road Markers and Stiles.
	Steel Frame and Corrugated Iron Gate and Header Boxes.
	Concrete Foundations Meter and Regulator Stations(150 Yards).
	Blocking on Main Line Headers, etc. (Concrete 300 Yards).
	Ottawa and Red Oak Warehouse Foundations (235 Yards).

Account Number	Description
	Insulation on Meter Runs—Ottawa, Illinois.
	Insulation on Regulator Runs—Joliet, Illinois.
	Gaskets, Bolts.
	Scattered Pipe Racks.
	Jetty Protection on Rivers.
	Drain Tile Used on Farms as Replacement.
	All 24-inch Main Line Couplings Including Welding Coupling Sleeves.
	All Pipe and Casing at Railroad Crossings.
	Linewalker Bridges Scattered along Line.
1006	Engine and Building Foundations, Floors and Reinforcing Steel.
	Pipe Rack Foundations.
	Blow-off Pits (Concrete).
	Cooling Towers and Cooling Tower Basins (Concrete) and Guy Wires.
	Concrete Septic Tanks.
	Sidewalks and Lighting Fixture Foundations.
	Manifold Blocking (Concrete).
	Fences, Gates and Cattle Guards.
	Roads and Curbs.
857	Evaporation Ponds.
	Landscaping and Shrubbery.
	Recreational Facilities.
	Insulation on Steam Lines.
	Signs, Steel Stairways and Grating.
	Water Wells and Original Casing (All Excepting Mechanical Equipment).
	Miscellaneous Plumbing Fixtures in the Stations.
	Grating in Floors.
	Lighting Fixtures, Conduit and Globes.
	Annealing Furnaces.
	Sewer Lines.
	Storage Batteries.
	Clothes Line Poles and Wire at Cottages.
	Small Oil Measuring Tanks.
1010	Signs, Walks and Roadway—Red Oak Warehouse.
	Lockers—Red Oak Warehouse.
	Fencing—Various Meter and Regulator Sites.
	Retaining Wall (15.2 Yards Concrete)—Davenport Line.

Account Number	Description
	Curbs, Sidewalks, Roads, Sewerage System Signs—Joliet Meter Station.
	Water System and Landscaping—Joliet Meter Station.
	Curb, Walks, Landscaping Sign—Joliet Regulator Station.
	Pipe Racks, Roads, Signs, Lockers—Ottawa Warehouse Site.

Texoma Natural Gas Company

Non-Salvageable Property Not Listed in Exhibit #122

Account Number — Description

1002 Telephone System Right-of-Way Easements.

1004 24″, 18″ & 16″ Pipe, Valves & Fittings and 24″ Couplings.

858 Concrete Anchors on 24″ Pipe.

Cattle Guard, Gates.

Various Types of Drips and Headers.

28″ Highway and Railroad Crossing Casing.

Approximately 200 Yards of Concrete in Building Foundations.

1005 All Main Line Couplings, Including Welding Sleeves over Couplings.

All Main Line Meter Headers.

All 28″ Casing Pipe Railroad and Highway Crossings.

Concrete Anchors on Main Line.

Pipe Racks.

1006 Engine and Building Foundations, Floors and Reinforcing Steel.

Pipe Rack Foundations.

Cooling Towers and Cooling Tower Basins (Concrete) and Guy Wires.

Concrete Septic Tanks.

Sidewalks and Lighting Fixture Foundations.

Manifold Blocking (Concrete).

Fences, Gates and Cattle Guards.

Roads and Curbs.

Account Number	Description
	Landscaping and Shrubbery.
	Recreational Facilities.
	Insulation on Steam Lines.
	Signs, Steel Stairways and Grating.
	Miscellaneous Plumbing Fixtures in the Station.
	Grating in Floors.
	Lighting Fixtures, Conduit and Globes.
	Annealing Furnace.
	Sewer Lines.
	Storage Batteries.
	Clothes Line Poles and Wire at Cottages.
	Small Oil Measuring Tanks.
859	Gasoline Service Equipment.
1007	Concrete Blow-off Pit.
	Building Foundation and Floors.
	2 Air-Cooled Settings for 500 H.P. Water Tube Boilers.
	200' Reinforced Concrete Chimney.
	Concrete Walks and Curbs.
	Evaporation Pond and Pits.
	Miscellaneous Plumbing Equipment.
	Miscellaneous Shelving and Cabinets.
	Steel Grating and Steps.
	Concrete Foundation of Material Storage Platform.
	Concrete Foundation of Pipe Rack.
	Concrete Septic Tank.
	Absorber and other Tank and Tower Foundations.
	Foundations on Chlorine Rack.
	Ice Making Equipment.
	Salt Storage Tanks.
	Insulation of Piping and Various Equipment.
	Lighting Fixtures, Conduit, Globes.
1010	Curbs, Roads, Sidewalks.
	Cabinets, Clothes Lines, Shelving.
	Cattle Guards and Pipe Rack Foundations.
	Foundation for Storage Platform.
	Corrugated Iron Tool House and Garage and Wood Frame Water Well House, Kingsmill.
	Concrete Septic Tanks.
	Water Wells.)

860 *Cross-Examination by Mr. Booth.*

The amounts shown under the caption "Original Cost" on page 22 of Exhibit 122 represent the cost which the company paid for that equipment when it was purchased. The cost of the motor itself is the amount stated. I went to the books and got the figures shown in this exhibit, that is, I had my organization do so, and in that connection I instructed them to obtain the book cost figures for the material which is to be salvaged. The freight is not included in the items shown in this exhibit. Only the bare cost of the items as shown on the books is shown throughout the exhibit. I would like to make one explanation in this connection. Some of the buildings, the main buildings for instance, were purchased erected. Now in that case, freight and labor of erecting were included in the purchase price and reflected in the original cost shown by the books.

The amounts shown under the caption "Original Cost" on page 27 relating to tanks represent only the cost of the equipment, as to all those small tanks. There is a question in my mind as to the elevated storage tanks. I believe that those tanks were purchased erected, but that is immaterial since those tanks are not affected by the figures shown under the column "Original Cost", as they are among the items to be salvaged on a weight basis. I am speaking here of the nine 100,000-gallon tanks, weighing 212.66 tons.

Cross-Examination by Mr. Slaff.

Whenever freight was paid by the company it is not included in the original cost figures, and no other overhead and no interest during construction or expenses of that type are included in such figures, only bare original cost; only the amounts received by the seller from the defendants are reflected. (Objection and motion to strike by counsel for Illinois Commerce Commission overruled and denied.)

861 HERMAN P. TAUBMAN, a witness for the defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 30, 1939.)

My name is Herman P. Taubman. I live at Dallas, Texas, where I have lived since the early part of 1938. Prior to that time I lived for eighteen years in Tulsa, Oklahoma.

Before going to Tulsa I was employed by a junk and salvage company in Joplin, Missouri, for four years from 1916 to 1920. This company was the Joplin Iron and Metal Company. It was engaged in buying mining machinery and breaking it up, that is, any part of it that could not be resold. We also engaged in the resale of second-hand mining equipment. They were considered the largest dealers in their line in the Southwest. They bought and broke up large crushers and compressors and the engines that supplied the power for the plants. These plants were mining plants that extracted zinc and lead from the ore, or rather from the boulders brought up from the ground. These boulders were crushed up into what we call tailings or gravel for the separation of minerals. They employed heavy machinery in these operations.

When I went to Tulsa I entered the oil and gas supply business, mainly in connection with the pipelines, buying and selling of pipelines and abandoned leases, oil and gas wells that were exhausted, and putting the material on the market for sale as salvage. I went to Tulsa in 1920. I started with a strictly second-hand business in pipe and machinery, but later I specialized in pipe alone, and machinery was a side line. For a period of three years we had given no specialty to either pipe or machinery, depending on whatever came our way. At the end of three years we changed our policy and specialized in pipe because we felt that machinery, no matter where it was located, in all instances had to be brought into the plant at great expense. It had to be overhauled, tested, and sold with a guarantee of performance. We had a great deal of it come back on us because parts which would not be reconditioned would give out afterwards. In other words, making good on the items we sold cost us too much, and we finally had to quit dealing in such machinery.

Thereafter we handled it only on the basis that when the pipeline or lease was offered us for sale and we could buy it and figure the machinery and equipment on a junk basis, so that we could break it up and ship to the nearest market, we took it. Otherwise we refrained from purchasing some of it if we had to sell it as usable items.

My business continued strictly second-hand until the
early part of 1926. Thereafter we found that the market
for second-hand pipe was getting more difficult, due to the
newer types of pipe and the greater capacities of the steel
mills, which made the sale of second-hand pipe material
and its turn-over difficult. We had to add new pipe
862 in order to remain in business. In 1926 our business
was divided between second-hand and new material
about half and half. The second-hand business kept going down until the three years at the height of the depression when of course there was very little business, if any, and at that time the second-hand business was practically the same as the new. In normal times, after the depression lifted somewhat and business improved, in 1936, when I sold my business to Bethlehem Steel Corporation, 85% of my business was in new material and about 15% second-hand.

I operated the business about one year for the Bethlehem Supply Corporation, a subsidiary of Bethlehem Steel Corporation. There was a reason for this decreasing percentage of second-hand business down through the year 1937. The constant increasing cost of labor and the improvement of new material rendered second-hand pipe impractical because of the ratio of saving in the price we had to charge for second-hand pipe, that is worked over and shipped later for a specific purpose, in relation to new pipe. The prices were so close that the buyers did not consider the second-hand pipe. We get a greater number of buyers for the smaller sizes of pipe, such as 12 inches in diameter and under, than for the larger sizes.

I am familiar with the type of pipe as to dimensions and specifications used in the construction of the pipeline of defendants. I bid on a great deal of it, although I did not get the sale of it. I had the specifications to bid on and made bids in an effort to sell these companies pipe at the time they were constructing their line. Included in my pipe business, of course, were pipe fittings, such as gate valves, fittings, and accessories that go with pipelines.

Since I withdrew from the pipe business at Tulsa the first of 1938, I have been in the oil business. I have had oil interests for about eight years, of which I did not have personal charge. On leaving the supply company I took charge of my oil company, known as the Buffalo Oil Company, which is engaged in drilling wells for oil and gas.

I am conversant with oil field conditions down in the Southwest in the States of Oklahoma and Texas. I know the types of pipe that are being utilized, and I know the demand for pipe of different dimensions and qualities, as well as some of the machinery that is employed by pipeline companies. I spent over a million dollars for purchases of this nature of material in the last three years. From the beginning of 1921 I have kept a record of the pipe and machinery and related material which I handled. The volume amounted to more than $36,000,000. I have bought thousands of miles of pipeline in the ground and taken it up and put it in condition to sell as used pipe. This was not at one time, of course, but in the aggregate of years that I was in the business. The cost of taking pipe out of the ground and incurring all the expenses incident to getting that pipe loaded on the cars varies as to locations, as to depths, and as to weather conditions in working outside. It ran from $15 to $18 a ton.

These costs include a number of items. First it is necessary to get permission from the land owners to enter their property, and in most instances they make you pay considerable damages because they figure that when you get the line out of there, that is the last chance they will have to get anything from it. We find we have to pay a considerable amount more than was paid in the original 863 taking of the right-of-way from the owner. We find the farmers in a receptive mood to find damages for turned up crops, dead cows, and everything, and we have to pay them these damages even before they let us come in with our property.

Then we have to remove the pipe from the ground. Some smaller pipe we ditch by hand, by shovels, but in the larger sizes we have to use heavy machinery, such as tractors, ditchers, and cranes to lift the pipe on heavy trucks. We first have to ditch it, to uncover it, to get to the pipe. Then we have a crowd of men with shovels following to get to the pipe itself to get it free to be lifted. We then lift it up with a crane. If it is small pipe, we put men in there and let them shoulder it out. Even up to 6-inch pipe we handle it by hand, but when it gets above that we have to have cranes.

The equipment we use depends on the size of the pipe and the weight of the load we have to lift. We cut it with acetylene torches usually. This is an expensive operation. We have to have skilled men for the job, and the ingredients of carbon and all other requirements that go with the mixture in the acetylene, and the equipment itself is quite expensive, running into quite a cost. After we get the pipe on the ground we have to cut it in lengths to transport over highways in approximately 40-foot lengths and get it away from the ditch. Then we have to refill the ditch made in recovering the pipe. If the pipe is a large size, we naturally create an empty space there where the pipe is taken away, and if the land is flat it is necessary to fill it up and restore the ground in a usable condition to the farmer, whatever that condition happens to be. The specifications in the right-of-way grants require that the pipe be buried enough below the ground to make it safe.

Referring to the pipeline of the defendants, the places that I have looked at, even as late as two weeks ago, aside from knowing the specifications at the time the pipe was laid, I noted that the pipe is buried an average of five feet—some places may be four and some six, but the general average I would judge to be five feet in depth to the top of the pipe. I was really curious, and at the time I noticed the depth I inquired of the management why they went so deep, and they explained it was a high pressure line and they had to bury it deep to have the safety factor of the weight of the soil to hold it down.

In order to get the dirt off the pipe and get it out of the ground, it would be necessary to have regular ditching machines such as were used in putting the pipe down in the first place. They can come within an inch or so of the top of the pipe without hurting the machinery. Later it is necessary to follow with men and shovels to dig at least one-third of the clearance down the sides of the pipe so we can have it free enough and loose enough to lift it out of the ditch. In other words, it is a pick and shovel operation to get the dirt immediately off the top of the pipe and one-third down the sides.

When the pipe is lifted out of the ground by heavy machinery, as I have stated, it having occupied a cylindrical position there 24 inches in diameter, there will not be enough dirt there to fill the ditch back to its level at the time the salvaging was started. There is no dirt, I would say, in the majority of the territory without making a ditch by bringing it in from the sides. If we get the dirt along the pipeline immediately near the pipeline and fill the trench, we create a ditch condition. It is necessary, therefore, in order to satisfy the farmer
864 to haul in dirt to level the place where the line was taken up, or it would be necessary to leave a ditch even if you take dirt off the sides and try to level it up. In most instances we allow for the ground to settle, due to rains and washouts, so that we would not have to come back and repair the right-of-way, because we are always subject to damages for going in and breaking up the land. We build a ridge above the trench so as to allow for the ground to settle to a level.

If the pipeline happens to be on a farm under cultivation, the farmer definitely will not let you take the top soil off his cultivated field to fill up this ditch. It is necessary to bring the dirt from the outside, and the dirt left on the top of the field must be as near as possible the same type of dirt he has there. In other words, he will not let you bring in any rock and gravel and road building material to fill in with because that would ruin his land. He wants to go on cultivating after the pipeline is removed and requires some soil that will conform as near as possible to the soil on the rest of his land. If the land is not restored to approximately its original condition, it means more damages than the damages alone of going in there with your machinery in the first place. You never hear the end of it unless he is satisfied. I have had lawsuits to pay for months after we lifted the pipeline. In one case the farmer even accepted the backfill when we left. He said, "It looks all right to me." Some months later we found he had a cow that got hurt, that broke its neck. He said the rains came that he did not expect and washed it out. Unless you leave the right-of-way in a safe condition, you are responsible for any damages that may result therefrom.

When we have got the pipeline on the ground cut up into 40-foot lengths, we have to lift it up from where it is and take it to the nearest railroad point for shipping. If it is coated pipe, a pipe that is coated with bitumastic covering, we have got to take it off. Bitumastic covering is a pipeline coating for its protection. If you are going to sell it for pipe, you have to clean it off so the man who is buying it would know what he is getting. He would not buy it like a cat in a sack. He would want to know the condition of the pipe before he bought it, and you would have to take this covering off. You would have to get special machinery because this type of coating is a sort of enamel. It cannot be handled by hand. There is machinery in existence for that purpose. It cannot be removed with sandpaper like varnish or paint off of furniture or off of wood, unless you wanted to be there for the rest of your life. If you want to take it off economically, you have to use machinery for it. That is an expensive operation. It is big pipe, weighing 83 pounds per foot, and a 40-foot length would make it over a ton, and you have to have a crane or machinery erected at each loading point, or you have to have an army of men carrying that pipe, and in either instance it is an expensive operation.

For the removal of this enamel the pipe must be moved to a location flat and dry, and this is usually at the railroad. In my judgment there is not enough ground in the country where the pipeline could be taken that would accommodate that much pipe. It runs into too much stack space alongside the railroad. Unless you have an immediate outlet where you could move it out of the way, I doubt that there is any one point on the entire line that you could get enough space to stack this pipe and work it over and lay it away for later shipment.

865 In order to get it to the railroad for cleaning it has to be trucked with heavy trucks. It cannot be trucked as ordinary material, such as the smaller items concerning which Mr. Smith and Mr. Davidson were testifying here yesterday. It is necessary to have heavy pipe trailer trucks to handle this type of pipe. That type of truck usually has what we call a winch, or else you have to use a lot of labor, unless you have a crane. You can hardly use a crane in the loading because the crane would have to be on the other side of the ditch, you know, and it would just

be impossible. It would be necessary to use a lot of manpower and skids to roll it up on. This loading and trucking would cost between $3.50 and $5 a ton, depending on the distance.

After it has been taken to the railroad site where the cleaning machinery is located, there is other cost involved in getting it on the railroad car ready for shipping. The cost depends on what you are going to ship it for. Before you can ship it, if it is to be used after cleaning it off, it would be necessary that it be again coated with what you call an iron paint protector. Otherwise the pipe would become rusted and would not be merchantable. That is necessary if you are going to dispose of it as used pipe. In addition to that, the ends must be beveled for welding, because in cutting it at the ditch it is practically impossible to make an accurate cut so both ends will meet again when you are relaying it, and therefore you have to go over it again and trim the ends suitable for rewelding, what we call beveling for rewelding.

Pipe that has been bent in going over hills and across valleys and around curves and things of that kind it would be definitely impossible to straighten out and make a merchantable job of it without its costing more than making new pipe. That pipe could not be cleaned off with the some machinery with which straight pipe is cleaned off. You can only accommodate straight pipe traveling over rollers, pipe that fits the machine. It must be straight or it would not go through the rollers. This bent pipe would not be fit to use if you cleaned it by some other method.

After getting this 24-inch pipe out of the ditch and paying the farmer his damages and meeting his requirements as to refill and so forth, and after trucking it to the railroad and cleaning this pipe of its enamel, such of it as is straight, and after rebeveling it and preparing it for welding again, the pipe is then ready to be loaded on the railroad car. Since it is exceptionally heavy and is built for a specific purpose, my experiences have been that we have never bought or sold any amount of it worth mentioning of this size of pipe in such weights as that, or, in fact, very little in any weight of that size, because it is an unusual size for oil and gas use. I have had very little experience in handling 24-inch pipe in my business down there. I purchased about a mile of it from the A. O. Smith Corporation in Milwaukee, Wisconsin. They had it left over from an order that they filled and had it in stock for three or four years, having no calls for it. They had to have space when they went into the manufacture of casing, and they asked me if I would buy it with other sizes of large diameter pipe. I bought, as I recall, close to 1,000 tons in all, of which the 24-inch was about 200 tons, or a mile in aggregate length. Well I held it there. I moved it from where they had it and paid for the moving in order to get it out of the way. They had sold it at a low figure because they wanted to get rid of it, and the understanding was that I would move it. So I moved it to the lower end of their plant, and finally, after a year nearly, they got tired of looking at it and called on me to remove it.

866 I shipped it to Houston. It happened that I had more space to spare there at that time. I held it there nearly a year and had to clean it again before it was merchantable. Finally I sold it to the Humble Oil and Refining Company for a gasoline plant where they wanted some low pressure pipe. The specifications I think were 22 inches, but I gave them 24 inches at the same price at the low weight figure in order to move it. In other words, there was a job where they could have used 22-inch specification work, but the larger size in this particular instance did not interfere, and they were getting heavier pipe for the same money as light pipe. It took me two years to get rid of a mile of pipe which I bought new at a second-hand price because the manufacturer wanted to get rid of it. I don't suppose I would live long enough to get rid of 900 miles of pipe of this character.

Taking into account this cost of removing the pipe and getting it to the railroad, which I have stated would be from $15 to $18 a ton—and in my judgment it will cost that to get it there, I am basing that on the cost of small sizes, with less difficulty, with less equipment used. I am not raising the figure. It could be done with a safety factor in this size of pipe. My reason for saying that is because the heavy weight involved in the pipe would be offset by the greater tonnage taken up in a day's work with the same crew that would take up small sizes, and therefore I am not using a higher figure, which should be allowed based on the extremely large size of the pipe, the extremely heavy weight in handling.

In my eighteen years in the pipe business I would say that for the first ten years I do not recollect having a single call for 24-inch pipe, and for later years, when the greater number of gasoline plants began to be built with what we call a low intake pressure, we got occasionally calls for 20-inch and some 22-inch and once in a great while 24-inch for extremely light weight pipe. There are manufacturers who make that pipe. That is not the same type of pipe that went into defendants' pipelines. They do not require the same specifications for this low pressure use out at the fields for the gathering of gas to a natural gasoline plant that are required by these pipelines in transporting gas under high pressure. As I recall, it is 50 pounds of pressure going into the line, and what we call a stovepipe weight would be sufficient, and that is what they asked for.

I do not remember ever having had a call for used pipe of the specifications of the pipe used by these pipelines. There is a market for 16-inch and smaller light weight pipe used in the construction of gasoline plants, but there would be no market for this heavy 24-inch and 22-inch pipe. In my judgment second-hand pipe would not be used, even if there was a line of this type of pipe contemplated being built elsewhere. In fact, I have never had an inquiry for a permanent high pressure line where they would take second-hand pipe. This is for the reason that the life of the pipe, based upon metallurgical figures, would not justify the expenditure of constructing the line at this great expense, having in mind that the pipe would not last during the same life that new pipe would. There is a lot of expense involved in the laying of a pipeline besides the purchase price of pipe. A pipeline would only be constructed by people of financial means, and under no circumstances would an engineer specify or even accept at any price a line of this type after twenty years' use, regardless of the looks of it.

867 The only market disposition that could be made of the steel in these pipes would be a market for such use as road crossings and use for such gasoline plants as might be built where they could use light weight pipe. In such competition, even if there was a fair market for this heavy pipe, taking it out and preparing it for use and shipping it to the point it might be used at, in some instances would be local shipment, but assuming it was carloads, the freight from the point where most of this line is located is almost as high a rate as it would be from the steel mills, and in some instances a greater freight rate, because the ordinary railroad points do not have what we call a common point freight rate for pipe and equipment such as to compete with the steel mill must be set up. Therefore, it would cost

you more to send this pipe to where it might be used than new pipe from the mill that is made to the specifications, which would be just as acceptable for other purposes as this heavy weight pipe. In fact, it would be more suitable because in constructing lines in the field which are usually short they do not equip themselves with the type of equipment that would be required in a line of this type. Naturally, since it is extremely heavy pipe, it would not be as suitable for that purpose because they would have extra expense in laying it.

In other words, my judgment is that from an economic standpoint, it would be utterly impossible to condition and market this pipe within a reasonable length of time.

We have overlooked one factor, and that is the tax. The minute we take the pipe out of the ground and bring it to the railroad station we find the tax assessors counting the joints of pipe and sending us a bill for it. I have had an instance where I took out a line and brought it to the railroad point in Oklahoma in Pawnee County. We came in early in February to move the pipe and there was a sheriff's notice: "Do not touch this until you pay." I think it was three hundred and some odd dollars for tax. So our counsel went over there, and they told him that anything that was in that county since January 1st, if it was unloaded, would be taxed. He said, "You pay me for a whole year or I will not let you take the pipe." We had to pay before we could move the pipe. In taxing the pipe he values it alongside the railroad and not in the ground.

In addition to the slowness of its moving and the tax, there is the safety standpoint of children getting on this pipe and getting hurt. All that would cost more than you could get out of it. The only practical solution from an economical standpoint would be to take this pipe up and ship it to the Chicago junk market and sell it to the steel mills for melting back into steel. In order to do that this bitumastic covering would have to be removed since it contains a chemical which would be injurious in the melting of steel, and no steel mill to my knowledge will accept it as scrap steel for remelting until that is removed.

Then you would have to pay the freight rate to Chicago. You get it into the yards in 40-foot lengths in pipe of these dimensions. It would then have to be moved into some yard which is equipped to get this pipe into specification melting sizes for steel scrap. This unit is called cupola size. This refers to the cupola in which the steel is remelted, and they

have to cut it into slabs 18 inches wide and 5 feet long to accommodate open hearth furnaces. No steel mill would take it in 40-foot lengths. It would have to go to a dealer's yard, wherever you could find one that is equipped for it, in Chicago or other markets. Naturally, the closer to
868 the shipping point, the more you would reduce the freight. In my days we were forced to use acetylene torches to cut this pipe into these small cupola sizes. I understand now they could build a machine if there was much tonnage involved, whereby they could flatten it in one operation and then cut it with the machine, thereby reducing it to $4 a ton. Cutting it by torch would cost about $7 a ton. The prices quoted in the publications and shown in this Exhibit 122 are the mill prices quoted in the Chicago Journal of Commerce and the Iron Age that we used to go by. There were three or four such publications. That is the market at which the steel mill would be interested in buying this pipe or these chunks of pipe for melting purposes. The record shows that at the present time the price would be about $11.38 a ton. Instead of making money salvaging this pipe and putting it in shape to sell to the steel mill, you would lose about $13 a ton on it.

The cost of bringing it to the railroad would amount to at least $15, the cost of cleaning it to $2, and assuming the place that you break it up will be near the steel mill, the freight, I understand it, would be on the average of $4.40 a ton. This would bring the cost of getting it to Chicago up to $21.40. The cost of cutting it into cupola lengths would be another $4 a ton, bringing the total cost up to $25.40. This would show a loss of $14.02 a ton. As a practical proposition, it is impossible to recover that pipe economically. My judgment would be, if your right-of-way terms would permit it, to leave it in the ground. That is the only salvation without going through a tremendous loss.

As to river crossings, our practice has always been to leave the steel there. The costs were always greater than the material was ever worth after recovering it. I never heard of any one's salvaging a river crossing. Those that we did do we never told anybody about them. By river crossing I mean the river line, the pipeline across rivers and streams. The line headers would be obsolete and there would be no market for them as used equipment. They would not be worth anything to take down for the money they would bring as scrap. The gate valves were specially made for this purpose, and there is no market whatever for any other use. If you have to leave the pipe in the ground, you would leave those in the ground because they would not bring the price for junk that it would cost you to take them out.

In Exhibit 122 all types of gathering line pipe and fittings, including valves and other fittings that go with the pipe, outside of the 24-inch line are valued at $20 a ton. I gave Mr. Davidson that figure. It is based on purchases which have been made for about ten years of similar grades of material which were in rough condition coming out of the ground. It is not possible to clean up, recondition, and resell for further use all of the equipment of this kind that comes out of the ground when a pipeline is salvaged. None of it is suitable for immediate reuse without work cleaning up, testing and replacement. In the case of gate valves, you would have to bring them into a machine shop, take them apart, replace the parts that are worn, reseat the rings, and later test it again for whatever use you are going to put it to. In doing so the percentage of at least one-third is usually discarded as not being suitable for working over. Not until you perform considerable work and incur considerable expense can you determine whether it is suitable or not. We go through with the work and expense of taking it up and hauling it to the train, and shipping it to the central places before we find that out in many instances.

The same observation applies to the pipe. It isn't
869 suitable to be used immediately without being taken
into a central point, cleaned up, checked and tested, and the ends rebeveled for welding, and whatever percentage isn't suitable for reuse has to be discarded as junk.

Bent pipe of 12 inches or less in size can be straightened if the body is sound and in usable condition, but this straightening involves a cost, depending on the size of the pipe and the amount of bends or kinks to be taken out. There is regular machinery, similar to the cleaning machine, only it operates with a hydraulic press, which is used in the straightening process. It is a hydraulic system, whichever way it operates, whether by hand or motor, and the pipe is put in the straightener, and there is a half round shoe that comes down on the pipe in the crooked places to straighten it. Light weight pipe, 12 inches down, can be straightened cold. Heavy weight pipe has to be heated either with building a fire from wood, or a torch has to be applied before you can straighten it. In other words, the strength of the pipe is so great that if you force it with hydraulic jacks without softening the metal, it would throw the pipe out of roundness and render it worthless. In order to maintain its roundness you have got to soften the metal, make it flexible, so that it will straighten out.

It is seldom that you are able to recondition and sell more than 60% of the pipe that comes out of the ground. That doesn't mean that all of that is what you would call 100% good, suitable pipe for the same purpose. It would do for a lighter use purpose than it was originally intended for.

There is a corresponding loss by unfitness for further use in other types of these fittings besides the pipe itself and the valves that I have mentioned. There are many reasons for this. For example, most of them are made out of cast iron, and they will be chipped off and defaced in appearance, in addition to the worn parts, and there is a great deal of obsolescence. A certain pipe is made for a specific purpose and would not be suitable for many other purposes. For gas line use I would say 95% of the pipe used is welded together. Taking welded pipe and cutting it into 40-foot lengths in the manner I have stated here in order to be able to handle it, there is loss in the cutting process and in the reconditioning or beveling of the end where the cut is. That is true even if the pipe came out sound from the standpoint of its condition. The weld originally made to lay the line seldom is cut right in the weld. You always cut a distance from it, leaving on one end of the pipe that part which has been previously welded, and in order to make it merchantable and suitable for reuse, that part has to be cut off and beveled for use again, and there is a loss of about 5 percent of the metal.

This taking up of pipe and pipe fittings of the various kinds that are listed in this exhibit and reconditioning them for sale as used pipe and fittings is a specialized business. There are quite a number of people in the business, but they all have to have equipment and central points to bring the material to and work it over.

In an instance like the Phillips Petroleum Company, or any other company which is continuing to operate in the field, they will take up lines and sort them out and do the same work as the dealers do. They will then pick out what
they can use and bring it to such points as it may be
870 suitable for, and they do not sell that unless it is a
tremendous amount more than they need. The same

people, however, do sell, and I brought many millions dollars worth from major units which do use the same kind of material in their operations, either the operations for which the material was originally intended or any other branch of the industry, but by reason of the freight factor and the handling, they will at times sell. I happened to buy a gasoline plant and the lines from Phillips in Roswell, New Mexico. They at the same time were doing work in Kansas. It would have been entirely prohibitive from a cost standpoint for them to take this particular plant and move it over to Kansas, so they bought new material and some second-hand material I had to sell there. They sold me the New Mexico stuff as it stood. They turned it over to me, and I took it out of the ground, cleared the location and shipped it where I had a market for it.

In other words, some of the oil companies which have this type of equipment which they can move within limits from one place to another build up organizations for the purpose of doing the same thing that the dealer in second-hand material of this kind has to do. They have a man in charge of that particular department that uses the same machinery we do and goes through all of that. Of late, if I am permitted to state, I have investigated personally among the oil companies and dealers and find that they are discarding this practice by reason of the fact that it is unprofitable to maintain any central point for shipping material to, and handling and labor and freight are eating up the worth of the material compared with what they can buy new material for as and when they need it.

Even those companies like Phillips Petroleum Company, which have built up organizations and have acquired equipment necessary to recondition pipe and pipe fittings of this character do not recondition the material but sell it to a dealer who is equipped to do that. This dealer must know its condition before he sells it. I would say that in a case where the Natural Gas Pipeline Company and the Texoma went out of business after the gas gave out, they would definitely have to sell it to some one who is in the business, because economically it would not be possible for them to organize such type of organization to do this work and carry on the sales for the length of time that would be involved to get rid of it. I am talking about these gathering lines and pipe fittings that go with the gathering lines, which are listed here in the exhibit, the small pipe and small pipe fittings of the character listed here, on which I have placed a $20 valuation. This valuation covers this type of material after it is taken up and put on a car and I had a chance to see what I am getting. I would not pay that kind of price for the material in the ground and take it out. The fact of the matter is, based on today's conditions in the market, I wouldn't take it as a gift in the ground where it is now.

I heard Mr. Davidson testify that in applying the arithmetic which is used in making up Exhibit 122 he had applied a freight factor of $4.40 a ton from all points up and down the line except Joliet, which is near Chicago, and Fritch, which is down in Texas, and in those two instances he used a freight cost of $1.06 and $7.20 respectively, and that he had used a hauling charge of $3, and that the balance of the cost involved in the reclaim was to cover what he termed "demolition." I supplied those figures to
871 Mr. Davidson for this exhibit, based on my experience
of demolishing engines and pumps and tanks and scrubbers, and material of that type, perhaps not as big as those, particularly the big compressors that are described here, but for a similar nature of work. By demolition I mean breaking them up into parts that can be handled as junk and sold as junk at the full market price. We use three levels of demolition: $7 in the case of what he termed melting steel; $5 for these large units and other units composed of what he termed fixed scrap; and $2 for some of the small castings which can be demolished with a sledge hammer without the use of heavy equipment. I supplied those figures.

In order to demolish a 100,000-gallon or 200,000-gallon water tank set up on stilts and cut it into cupola sized pieces, we generally have a group of men around there to keep every one out of the way, and then we apply the acetylene torches to the props or legs that hold up the tank. We manage to knock it down to the ground and then apply the torch in cutting it up. We have to cut it with a welding torch which burns its way through the steel. Steel products cannot be broken up with dynamite or a sledge hammer. We have to use a torch on them. If you start shooting a steel plate you will get killed. You might, in light weight steel, make a hole in it, but the idea of dynamite breaking is not only to break an immediate spot, but it is the amount of cracking it does to the whole structure. It will not crack steel. The acetylene torch is the accepted way of cutting down these large steel units into cupola sized pieces so that they can be sold as scrap.

You have to use skilled men who know how to operate torches. My experience is that this process involves a cost of from $7 to $10 a ton, depending on the size of what you are breaking up and cutting up and the thickness of the metal you are working on. The same type of torch is used as that used putting it together by an acetylene weld, only you use the tip of the torch for welding and the other part is used for cutting. The same ingredients are used, and practically the same type of training for the men is required in either operation. These torches require skilled men who know how to operate them.

When we come to one of these big compressor units we find that the shaft is steel, the piston is steel, and probably the lettering around it, and some of the supports. The remainder is casting. The castings are usually so heavy, that is, the majority of them are so heavy, that you can't use a sledge hammer on them, and to get anywhere with it you will have to apply dynamite. The steel shafts and other steel parts you will have to use the torch on. That same performance applies to that type of salvage as it does to the tanks and the scrubbers. We find that the cheapest method and the quickest method to demolish big cast iron engines or crushers or pumps, or whatever they happen to be, when they are too heavy for sledge hammer work, is by the application of powder, just the same as you use dynamite in dynamiting rock or anything else. That is not the safest way, but it can be done, and that is the way we have been doing it. It requires skilled men for the purpose, who know how to handle powder and who use judgment as to loading, so that it won't fly in every direction. I tried it myself and had several narrow escapes until I learned how.

In order to apply dynamite to castings you find a flat spot on the metal so it won't roll off, something that you have a hold on, and you apply the amount of sticks of dynamite you think it will take to do the job, and fix it with a fuse and cap, making the fuse long enough to give you a chance to run away from it. Then you pack mud or wet ground, preferably a mixture of something that will hold, on the top. It doesn't have to be a big load, and if you taper it with something on the top it has a tendency to shoot downward, whereas if you place the shot right on top of the metal without anything on it, it will fly in all directions, and there is no telling where it will land.

Direct Examination Resumed by Mr. Morgan.

For an engine of the size of one of those involved here, you have to make quite a number of shots, because it is a large engine, and you don't expect that to blow up all at once unless you use a ton of dynamite, and then you wouldn't find anybody around there. Quite often we make shots and they don't take effect, and we have to do it over, or they don't break through, and we have to do it over.

Due to the heavy parts there is so much weight in it, we have found in our experience that it would run from $5 to $7 a ton, based considerably on how far you have to transport your men and if you have to board your men. If you have facilities locally, it reduces your cost. Where you have to bring them all in and take them back and feed them, that naturally brings up the cost. In this case, where your lines are located, in my examination recently, I didn't find a place where you would have for the men to do the work. You would have to bring them from somewhere and take them back.

Occasionally you find the type of men who are trained in this sort of thing and who are skilled in handling dynamite and these acetylene torches, and equipment of that kind, in the localities where these compressor stations up and down the pipeline are situated. But most of them you have to organize and bring in and give them a regular set-up to go on the job. It doesn't necessarily require that all of the men you use be skilled. You probably use on a job like this maybe 30 or 40 men, and you wouldn't need over a half dozen trained men. The rest of them can be ordinary laborers to do the work.

The small castings, water pumps, and things of that kind can be broken up with a sledge hammer, and each man can break from two to three tons a day, and maybe four. It depends on the place he works in and how accessible he is to the work. A man could swing a hammer all day long and break, as I say, from two to four tons. I figure to pay a man like that out in our part of the country about $4 a day as a common laborer. But you have insurance to carry,

and you have to feed the men and bring them in, and so if he averages three tons a day he costs you $6 at least, and thereby I arrive at the figure of $2 per ton. That is in line with my experience in junking that kind of machinery. Those other figures of $5 and $7 are in line with my experience also. In all these figures I tried to use the lowest figures in our experience, because there is to be considered that this will be a big job, and you can organize crews to go on these jobs that would reduce your costs to some extent, compared with your costs if you have just got to pick up a man here and there; for quite often you don't
873 get the right kind of men to do the work. In my judgment these are the minimum costs, and if any additional tax, such as Social Security and any other tax, may be added to the labor cost, that, of course, would raise these figures.

In the course of my experience going out and buying pipelines and pipeline fittings and other equipment, in which I dealt for a number of years, as I have stated, I have run into wooden cottages such as you see in the compressor station sites of these pipelines. In every instance there are from one to ten houses. In the nature of the business you have to provide permanent families with a place to live at the work. I didn't make a specialty in dealing with this type of equipment, but there was always that type of material, or I called it part of the salvage problem which we found in every deal when we could buy a "clean-up." I mean by that that we had to buy the whole place as it stood, including houses, offices, and garages. Such cottages have always been furnished and always will be as long as the companies have to provide permanent quarters for their men.

In our work, of course, we have had quite a number of leases or plants that we demolished in a district where other plants in other business enterprises were going on. In other words, it wasn't a district where everybody was moving, but was a going district like the Panhandle is today. We found occasional buyers, like a farmer who wanted a better house, or maybe there would be a small town nearby, and if the houses were in shape, they would buy them and move them over to the town, doing considerable repairs to the house. There never was a ready market for them. It has always been one of the things we didn't give a great deal of value to when we were figuring on the plant. We have sold them all the way from $25 up to $100, depending on the condition of the house and the location and the outlet we had for them. Sometimes we found it cheaper, rather than to leave a nuisance and be subject to damage suits, to put gasoline on it and burn it down, and in that way we would be better off. In most instances we found that the plant was located on leased ground, and the lease reverted back to the original landowner, and we used to make a deal, on my clean-up jobs, with the landowner for cleaning up certain parts of the work, and we would hire him to do that in order to get along with him. We would figure a house in for a little amount, plus whatever additional cash we had to give him, to clean up the location acceptable to him from the standpoint of the restoration of the ground.

I gave each of the houses, including 4-room cottages, 5-room cottages, duplex cottages, bunk houses, 5-room boarding houses, and office buildings a listing of $100. This is the most that I would figure any one would get for them, having as many of those houses. I gave them this value only because they are well built houses, and I am assuming that they will keep them up in good shape to the last minute. As far as the market in the Panhandle is concerned, as I know it, having a branch there for eleven years, frankly I don't know what to do with them, no matter what kind of structure they are. Sometimes a little community starts when the plant is built, and when the plant is moved, the whole thing moves because there is nothing else for them to live on. In that particular country, which has been the dust bowl that we know it to be, whole communities are isolated and the houses are boarded up and left standing there. I don't know what they will do with them. It is a shame. I was ashamed to figure a house as good as these at any figure less than $100.

874 Most of the people who live in that country live from employment in the plants built down there. They earn their living from the operation of the oil and gas companies and other industries which are dependent on these companies, such as gasoline plants, refineries, carbon black plants, machine shops, and other things that have to do directly with the oil and gas business. When the plant is gone, in a case where the company continues to function in business, they pick out some employees and move them to new locations, and those that they have no use for they turn loose, and they drift in every direction. They don't have a chance for livelihood where they are.

Cross-Examination by Mr. Slaff.

I have never testified in any other case on matters similar to those to which I have testified here.

875 E. M. SOLOW, a witness for the defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 30, 1939)

My name is E. M. Solow. I live in Dallas, Texas, where I have lived between six and seven years. For two or three years prior to that I divided my time between Pampa, Texas, and Tulsa, Oklahoma. Pampa is in the Panhandle of Texas, in Gray County. It is the county seat of that county. It is within what is commonly known as the Panhandle Oil and Gas Field.

I am Vice-President of the Western Supply Company, an organization engaged in the purchase and sale of oil field equipment, both new and second-hand. I have been associated with that company for the past ten years. For five years prior to that I owned a business of my own engaged in second-hand trading of oil field equipment, under the name of Solow Pipe and Supply Company.

The Western Supply Company has a store at Pampa. In connection with that store we have a machine shop and a shop where valves are reground and refaced and reconditioned so that they can be resold. We also have at that point a pipe shop where used pipe is brought in and reconditioned for sale.

At Greggton, in the East Texas field, we have a store and also maintain a pipe shop. At Wichita Falls, in North Texas, we have a supply store where we maintain a full line of casing, line pipe, and supplies. At Tulsa we have a large machine shop, rather completely equipped, where we can manufacture various oil field specialties, repair and recondition pipe, and things of that kind. These are all the places of business we maintain at the present time.

During the period when I lived part time at Pampa and part time at Tulsa I was engaged exclusively in the second-hand material business. To put the thing briefly, we trade in any kind of second-hand oil field equipment where we feel we have a chance of making a dollar. That means we will take oil field leases that have been abandoned, pull the equipment out of those, and salvage it. We take up pipelines and salvage the lines. We will buy warehouse stocks of valves and fittings and other equipment of that kind and divide them up among our stores. If they are used material, we will send them to our shops and recondition them. We are engaged really in a general used material oil field trade.

Oftentimes we have had to acquire residences or wood frame cottages provided for employees when we buy leases on which these structures are located, and we just get rid of them as best we can. We buy whatever they have if we think there is a chance to make any money on it. Oftentimes what these oil companies want to do when they sell a property is to clean the thing up completely. They want you to take possession and charge of it and clean up everything on it that is to be cleaned up, and turn the property back to the landowner in a condition suitable to him. That is the usual practice.

876 When an oil or gas well is drilled there remains in it certain casing, consisting of steel pipe screwed together in joints to comprise a wall for the well. If the well is drilled by the rotary method, which is one of the two general methods of drilling wells, there usually is a small amount of surface pipe, 100 to 300 feet, cemented from top to bottom in the top of the well, and then there is a final string which shuts off all formations above the gas or oil which is being produced from that well.

Wells drilled by the cable tool method, on the other hand, often start with larger strings of casings, and as salt water or other obstructions are encountered as that well is drilled, additional strings of casing are set from time to time. A cable tool well may have in it four or five strings of casing. When it is completed only the bottom string shuts off the last water or other formation which would interfere with the production of oil or gas from the well.

The two principal elements entering into the cost of the well, which this record shows ranges from $17,000 to $22,000 in the Texas Panhandle, depending on whether it is drilled in the Gray-Carson or Moore County areas, are the cost of making the hole and the cost of equipping the hole. When you drill a well you employ usually a drilling contractor who, for so much a vertical foot, does certain things. He sets the pipe, cements the pipe, drills the hole, and hands over the well in complete condition with the formation drilled under the instruction of the company's supervision. That usually represents about 70% of the cost of drilling gas wells in the Panhandle. The remainder of the cost is the cost of the material, principally the casing, which is placed in these wells. In the case of gas wells it is almost exclusively casing, and on top of these gas wells is placed a Christmas tree containing two or three gate valves and nipples.

When a gas well has served its purpose and ceases to produce gas in quantities justifying the owner's operating it, that 70% which the owner paid to the contractor is gone. There is nothing there but a hole which has to be filled up and plugged in accordance with the rules and regulations of the Railroad Commission of Texas, if the well happens to be in Texas.

When the final string of casing is set in a rotary drilled hole, it is cemented in place. The casing as first placed is merely hung in the well which has been made by the drilling contractor, and there is no seat, but in order to retain that casing in place and prevent leakage around the casing, it is cemented. This fills up behind the casing up to an approximate depth of, say, 1,000 feet, and is an additional wall to the casing up to that point. When you pull pipe out of a well you can't pull the cemented portion of the pipe.

The man who goes in there to pull this pipe moves his hydraulic jacks on to that pipe and takes tension, or stretches and measures the pipe. If the pipe is loose, say to the top of the cement, it will stretch eight or ten inches. If it is tied up where it can't be pulled one or two joints down, there will be practically no stretch. If he can only get four or five hundred feet, he will only have one and a half or two inches of stretch.

877 In the Panhandle there is a formation known commonly as salt. It is a formation that goes clear through the Panhandle from one end to the other. In Gray, Hutchinson, and Carson Counties you will encounter that at depths of 1200 to 1500 feet, depending on your well location. In Moore County, which is farther west, it will be found 100 or 150 feet deeper than in adjacent counties. That salt formation, when water leaks down into it, evidently ties that pipe up like cement, because it is practically impossible to get pipe out below that salt, and that salt is above the bottom of the cemented portion of the string.

In considering the salvage from these wells you have to look to this salt. I would say that the maximum amount of pipe you could expect to recover from one of these wells, taking the Texoma wells as a whole, is 1200 feet, but you don't always get the maximum amount of pipe. In many cases you get much less.

When I was in Amarillo last week a friend of mine, Don Harrington of the firm of Hagy, Harrington and Marsh, told me that they had recently drilled a gas well south of White Deer. It was such a small well they decided to pull the casing out, but they didn't get a single joint, when it had been in the well only a few days. In our own salvage operations we have had similar experiences.

So it is an entirely uncertain thing as to how much pipe you can really get, but for the purposes of this study I have estimated that we will recover 75% of the pipe above the salt, and frankly, I think that is a very generous amount to estimate. That is about 800 feet of pipe per well.

Ordinarily when you have pipe to pull from a well, you will employ contractors who are engaged in that business and who have the special equipment that is necessary, consisting principally of heavy hydraulic equipment to pull this pipe. Usually these contractors gamble in pulling pipe by taking a job on shares, but I have talked to every contractor in the Panhandle or have had our representatives up there talking to these men who are in the pulling business, and they confirm my judgment that no contractor would, or would have a right to, risk pulling these rotary drilled holes on shares, because there is only one string of pipe in them, and the amount of recovery expected is so little that it would practically cost them all or more than they could get out of that salvaged pipe to move in and do the job.

When the Texoma drilled these wells at each location there was a slush pit, which was built by the contractor, where he mixed his mud. When a well is plugged you have to fill that well with a mud-laden fluid sufficiently heavy to suit the requirements of the Railroad Commission. Usually this mud is taken from the old slush pit at the side of the abandoned well, but in this case there is no slush pit there. Texoma cleared that ground off as level as the top of this table. I drove around to I don't know how many of these wells, maybe fifty of them, all over the field, and I didn't see one evidence of a slush pit at any of those locations. They cleared them off after the wells were drilled. The contractors used them in making the well, but they cleared them off, I presume to avoid damage to cattle on the ranches in the Panhandle where these wells are located.

878 Now a contractor will have to haul mud and water and fuel oil to these locations. These contractors want various prices for doing this work. They range from $32 to $50 per 8-hour tour. After they find out how much tension they have on the pipe, they have to shoot off the pipe above the point where they estimate it will come, that is where it will start pulling out of the well.

In order to shoot off a piece of pipe 800 feet under the ground they have to drop dynamite in the hole, and sometimes it won't work and they will have to come up another 100 feet and shoot again. We have shot wells from a depth of 3500 feet to the top without the pipe coming loose and pulling. In other words, there is no question at all but what the actual cost to the pulling contractor for pulling the pipe out of these rotary wells will be $500, $600, or $700 per well.

Now in valuing the salvage of these wells in this report I gave Mr. Davidson this $100 figure. I allowed $100 for salvage for those rotary gas wells. I think it is an overstatement, and I put it in there because I believe it was a case where there were so many wells that there was a possibility that you might work out a little better trade with a pulling contractor and might get a small amount of salvage out of these wells.

There is one other factor I ought to describe, and that is the value of this pipe that is recovered from the wells. These wells are equipped, with one or two exceptions, with 8⅝ inch casing. This casing is either lapweld, electric weld, or seamless. Some of it is 28 pounds and some of it 32 pounds. I averaged the present new prices of all that material, and it figures about $1.55 per foot for the average value at this time of a joint of casing in one of these rotary wells. A second-hand dealer doing business and buying second-hand pipe would not pay at this time 77 cents, which is half the new price of 8-inch casing, but I have given that much credit for the pipe.

Now to haul that pipe from these locations, which are an average distance from the railroad of six or seven miles, and to ship this pipe from the Panhandle, because the oil and gas field will be abandoned when this system is abandoned, to a Texas common point, which is the cheapest place to which pipe can be shipped, will cost, reduced in terms of footage, 16 cents a foot. So that the value of this pipe to the Texoma for salvage would be 16 cents less than the 50% price I have indicated, or 61 cents a foot, and the value of 800 feet of this pipe would be approximately $489. If it is going to cost $500 or more to pull and plug the well and supervise the plugging of it, and furnish the cement for the plugging, the dynamite for shooting, and everything else that has to be done, you can see that there is no real salvage to these wells.

There is a difference in the salvage situation of those wells drilled and completed by the rotary method and those which are drilled and completed by the old method of using cable tools. These cable tool wells have all the way from two to four strings of casing in them. I took the first 15 of these cable tool wells listed on the material reports of the Texoma and found that in these 15 wells there were
879 the following pipe: 973 feet of 20-inch pipe; 4,509 feet
of 15½-inch pipe; 6,956 feet of 12½-inch pipe; 16,529 feet of 10-inch pipe; 19,325 feet of 8¼-inch pipe; and 7,471 feet of 6⅝-inch pipe. This pipe is not cemented in the wells as the pipe I described in the rotary wells was, and you can recover a percentage of the surface pipe. I have been buying wells in the Panhandle for ten or twelve years or longer. We have drilled a number of wells out there. We have had experience pulling this pipe, and before I wrote these figures down I made two trips out there. I discussed it with the members of our organization and with our man in the Panhandle that does all the preliminary dealings in pulling wells and things of that kind, and I believe the figures that I am going to give you now for recovery are exactly in line with conditions as they will be found.

I estimate that we will recover 30% of the 20-inch and 15½-inch casing; 50% of the 12½-inch and 10-inch casing;—this is the pipe where the salt will be behind one of those strings—60% of the 8¼-inch and 6⅝-inch casing. The reason, of course, you will recover more of the latter strings is that they are protected to the depth to which the outside strings are set.

Wells of this kind are the kind of wells that pulling contractors will contract to pull and salvage for 50% of the salvage. It is usually a good thing to deal with them on that basis. They naturally want to get all the salvage they can and will make every effort to get every foot possible of it out because their profit and the success of their work depends on their ability to get a good measure of pipe recovery.

Using these figures of recovery which I have given you, we will recover 292 feet of 20-inch pipe; 1,353 feet of 15½-inch pipe; 3,478 feet of 12½-inch pipe; 8,264 feet of 10-inch pipe; 11,595 feet of 8¼-inch pipe; 4,483 feet of 6⅝-inch pipe.

This pipe will have to be handled similarly to the pipe pulled from the rotary holes. It will have to be hauled from these locations, transported to a dealer's yard at a Texas common point. In addition to that, this pipe will have to be repaired. Cable tool wells are drilled with the tools hanging down on a wire line or cable, and the tools flop around in the hole, and oftentimes they line-cut, that is, the side of the line whips a groove in the pipe. There is some cut pipe in nearly every cable tool hole, and that has to be discarded. Further than that, a good deal of this pipe in these cable tool holes will have to be repaired in machine shops. Defective threads will have to be replaced with good threads. Swelled or damaged collars will have to be taken off and replaced with new collars. We have estimated the cost of shopping and throwing out junk pipe at $5 per ton. I think that is very reasonable. In actual practice the allowance for that is usually substantially more than I have given you.

In addition to that there will be a 2% loss in shopping pipe. In other words, when you cut off a thread to put a new one on, when you cut off a collar to put a new one on, when you have a joint of pipe that has been shot off and there is a shot hole in it, and you cut 6 or 8 feet off that so as to cut a new thread, this is all lost in handling that pipe, and the 2% that we have given to that is, I believe, far less than the loss you will actually find in practice and experience.

880 Taking all these factors into consideration, we next have to find out what this pipe is worth. I have allowed as the price of this pipe the maximum amount that we would pay today for this pipe if offered for sale at one of our stores where we are actively selling that size pipe. In connection with the large pipe, I want to say that from month to month, as fewer cable tool wells are drilled, the use for large casing is diminishing, and in some of our stores where we have 20-inch and 15½-inch casing in stock, we haven't sold 100 feet of either size of pipe in the last 18 months. So, while I am giving the top value which we would pay, I am frank to say that if we had to buy this pipe today, I don't think we would offer the price I have indicated for it because we wouldn't know what to do with it.

Those prices are as follows: the 20-inch, $3 per foot; the 15½-inch, $2 per foot; the 12½-inch, $1.50 per foot; the 10-inch, $1.10 per foot; the 8¼-inch, $.77 per foot; the 6⅝-inch, $.50 per foot.

I will also make the statement that within the last 90 days I believe we bought pipe of each category, small quantities of it, at less than the price I have placed on it in this salvage study.

When you deduct the 2% for pipe loss in shopping, the hauling of this pipe to the railroad, and the freight, and the $5 per ton for reconditioning that I have outlined, from the value of Texoma's one-half of this pipe at a common point in Texas, which value is $13,529, and since it covers fifteen wells, the net salvage per well for Texoma is $603. Now that is the average price on these fifteen wells. I think it is a very fair average of all of the cable tool wells of the Texoma in the Panhandle.

There is a progressively declining demand for used oil field casing. Fifteen years ago the majority of wells drilled in the oil country were drilled by the cable tool method, and in drilling wells by that method they would use three or four strings of large casing to shut off upper stratas of water as the well was being drilled. These strings were not particularly long. It was not particularly dangerous to run used pipe in these strings because they hadn't yet reached the oil or gas bearing formations. Usually companies that drilled wells used and reused various strings of surface pipe, and would buy new strings of pipe for the final string which they left in the hole as they pulled the others out. Sometimes they couldn't pull the others out and from time to time would have to replace their surface strings of pipe, so there was a demand for considerable pipe in every well that was drilled.

Under the rotary method you set a small amount of surface pipe to shut off the surface quicksand or water, or whatever is at the surface of the hole you are drilling; then you wind up with one string of pipe at the bottom of the well, protecting the oil or gas which you had discovered below this string of pipe.

The average cost of drilling a well in the Panhandle is $20,000. On the Gulf Coast of Texas it may range from $45,000 to $50,000. In some cases wells down there cost $150,000 or $200,000 to drill and complete, wells that range in depth from 8,000 to 12,000 feet. You can't conceive of an operator risking the investment in that hole by trying to

get a small saving by using for his one string of pipe
881 which is in that well used material. So you just have to find your customer for used casing among small outfits that aren't financially very strong and have to make every saving they can and who are willing to take the chance in completing a well in setting a string of used pipe in it.

Another thing, as drilling goes on in the Mid-Continent field, wells get progressively deeper. Twenty years ago the average well was drilled, I suppose, to a depth of 2500 feet; fifteen years ago to 3000 feet; today the average well is probably 1,000 or 1,200 feet below that. As deeper wells are drilled, you require better materials. You require materials with greater factors of safety, that will stand more tension and are just better made all the way around, and naturally when you pull out the material from old wells, you are just going to have a hard time to find a proper place to put it in current operations. Even today, if all this 8-inch pipe were pulled from the Panhandle, it would be a very difficult matter to go over all the oil country to every field that is being drilled and find a place where you could dump that pipe to be resold as casing. I don't think you could do it.

Leaving the wells and starting out towards the Fritch station we immediately run into what we call the gathering lines, or the lines which transmit this gas from the well head to the main gathering line, which in turn takes it to the initial compressor station. I have had experience in handling that type of equipment, gathering line pipe of the dimensions of that used by Texoma. We are constantly selling gasoline plants, which are being built all over the country, light weight pipe which they use for gathering lines, vacuum lines, residue lines, and so forth—pipe of the size and similar weight to that employed by the Texoma Company. A little different situation obtains with reference to this type of equipment than that of the gas well equipment. There is a limited market for used valves, for used fittings, and for used pipe. Before any responsible organization, however, will sell that kind of equipment to the trade, they naturally want to put it in first class condition.

I helped prepare this salvage estimate on those lines, and I placed a value of $20 per ton upon all of the pipe, 12-inch and under, and all the valves and fittings in the gas pipeline of the Texoma system. That means that we would take up approximately 11,000 tons of scattered pipelines running in size from 4 inches to 12 inches, that we would pick up out of the compressor stations and out of the lines some 6800 tons of assorted fittings of every kind, nature, and description.

Now that is a great quantity of fittings. I don't believe that all of the used material dealers in Oklahoma and Texas together will sell that many used fittings in a 2 or 3 or possibly a 5-year period. They might, because some dealer might get a large plant and find an occasional market for it, but these fittings will have to be sent to a machine shop and checked over. The valves especially should be reground and refaced and retested to such pressure as the supply companies selling them would be willing to guarantee to the buyer. The lines would have to be taken up, probably cleaned of the enamel that coats them, rebeveled for welding, and probably in some cases checked as to
882 test pressures they will stand, pretty closely. We have allowed a figure in these compilations of $15 per ton for doing this work. I believe that figure is very reasonable.

Let's take a concrete case to show what I mean. The 4-inch pipe weighs 7.63 pounds, approximately 8 pounds, per foot. If you take that pipe up out of the line and haul it to the railroad for an average distance of 7 miles, we estimate it will cost $15 per ton to do that job. Let's assume that $3 is the charge of hauling it to the railroad, which is a very reasonable charge for that length of haul. That leaves $12. With that $12 we have to ditch the line; that is, dig a ditch, and it is buried to an average depth, according to company records of 34 inches. We have to take the pipe out of the line, cut it into rough sections about 40 feet in length, and reditch the line. The pipe weighs about 8 pounds, slightly less, per foot, so we are getting less than 5 cents per foot for that operation, and it would be a hard thing to find a contractor to really perform that operation, or to do it yourself, for that 5 cents.

Similarly, you can take all sizes through the system. Therefore, I believe this $15 estimate, if anything, is on the low side.

The price we have estimated for this pipe at the depot is $20 per ton. New line pipe of this character sells at the mills today, and I am buying it for my company almost every week, at least some quantities of it, from the National Tube Company, or the Republic Steel Company, or some other manufacturer, at prices ranging from $45 to $50 per ton, and when you buy it in large quantities, as Texoma did when this was ordered, you buy it at prices approximately 10% less than the regular price. Therefore you can see that by the time this $20 a ton pipe is shipped to a point where it will be reconditioned, beveled, cleaned up, and offered for sale, that competing with new pipe it is going to be hard for the supplier who has ventured to buy the pipe and taken the risk of investing his money in it to make any money out of the venture. But I will say there is a possibility of a small salvage value in the pipe and in the fittings, and that is why we have given them these prices on these estimates.

I have seen some of Texoma's properties. I have been through the gasoline plant and the Fritch compressor station. I visited dozens of the wells in the field at different times, and last week while I was in the Panhandle I particularly went back to two or three of these wells to check up on the equipment around them and to be sure that I knew what I was talking about when I discussed them. I have been to the Gray station. I guess that is the Natural Gas Pipeline's station. I have been to the Joliet meter and regulator station. I have driven down to Geneseo on the main line in Illinois. I have driven to the Fox River crossing, I believe it was called, and have driven to the Mississippi River at the crossing of the pipeline near Muscatine, Iowa, and have examined the river crossing in the Panhandle on the Canadian River. I did not examine that last crossing particularly, but I have seen it a number of times when I have been in the Panhandle.

I took note of what they refer to in their property records as the steel frame buildings that are located at Fritch and these other compressor stations. I looked at those buildings carefully at the different places where I visited. Assuming the same type of buildings will be found at those other stations which I have not visited, I find that there is some salvage value to these steel frame buildings. Eliminating the foundations entirely, which have no salvage 883
value, you have the structural steel framework, the galvanized iron sides, the roofing, and the windows and doors of these buildings. These main compressor buildings are very large buildings. They are 68 feet wide, and the one at Fritch is, I believe, 244 or 245 feet long. The others range from 168 feet to a length 28 feet greater than that. Some of them were extended, as I understand it, in length.

These buildings are pretty high. I cannot conceive or find any ordinary use for these buildings somewhere else of the size they are now built. The buildings are too large. No lot would be just large enough to fit them. No industry would be just the right size to utilize them. The principal value of those buildings is the steel that is in them, the doors and windows that are in them, and stuff of that kind, and those buildings could be bought by a dealer who deals in buildings and refabricating them, using most of the material in smaller sized buildings.

Now as to these smaller buildings, two of them are too large for use generally, but most of them are what we call ordinary oil size buildings, the kind of building that can be used in building a new gasoline plant and for a dozen other purposes in the oil felds. Of course, they would have to be dismantled. If the buildings I looked at were fabricated any place, I believe they could be dismantled with somewhat more ease and facility, but the others would be more difficult. However, they all could be dismantled and shipped away to some other location where they could be utilized. That is why I gave 10% valuation to the smaller buildings and 5% to the larger buildings, and we based that valuation on the original cost of those buildings without taking into consideration the cost of the foundations. That represents my estimate, in round numbers, of what these pipelines will be able to salvage for those buildings.

I do not believe those roofs can be satisfactorily salvaged. I would just forget them. They are just waste like the foundation.

Occasionally you can find dealers in the larger cities who are engaged in the business of acquiring buildings of that kind. I do not know of a single dealer who is exclusively in that business in the Southwest, but a number of dealers down there will buy buildings if they can buy them cheap enough to make a dollar. Most used material dealers will venture into anything they feel they have a chance to make a profit out of if they know enough about it. There is a demand in the oil fields and perhaps in other places for that type of steel frame buildings. I believe that any one building a gasoline plant, or at least a large number of builders of gasoline plants, and others, maybe builders of small refineries or gathering station buildings, the small type of buildings, I believe would be a market for these used buildings of smaller sizes. This is the type of building that is ordinarily used in the oil fields for various oil operations. If the size does not fit one customer, it will probably fit the next one.

The reason for the difference in the attitude of the oil companies toward this kind of equipment and that toward casing that goes into the well and the pipe that goes into its pipeline, and things of that kind, is that when you drill a well the pipe or string of casing is going into the well and protect your investment. If, for instance, the string of pipe is lost, that probably is the end of the well. It is a
very expensive matter to repair such an error. For
884 example, since I have come here to Washington I have
learned that we were drilling a well ourselves, in which I had an interest, in the Camp Munger Allen oil field in Texas, and we lost a string of 26-pound casing in that well. The drilling contractor that was completing that well dropped his tools in the hole and broke the string of pipe in two in the hole. Just the pressure of the tools going down through the hole burst the pipe, and he had to set inside of that a string of 5-inch casing, a special size, which we had to order from Houston and rush it up to the well, and I believe it is now being cemented in the well. In other words, dropping the tools just accidentally caused $4,000 or $5,000 worth of damage in that one spot.

So you see a person has to be careful of what kind of material he uses in these wells. But a building is something that can be seen. It is on the top of the ground. If a truss, or anything else on it, goes wrong, it can be replaced by another. In the pipeline, where you put gas in the line under tremendous pressure, a break is a very serious matter. It costs a lot of money. It would cost more to repair than all the saving you could make by the possible use of a used valve or used fitting. You cannot take the same risk in dealing with casing, engines, or equipment such as we have been discussing here, as you can in the case of a steel frame building.

I have been through some of those cottages, duplex cottages, bunk houses, boarding houses, and office buildings. Those cottages have been figured in Exhibit 122 at $100 per cottage. When I first came to Chicago and went over the whole inventory with Mr. Davidson, I told him a house like that could always be sold to somebody or other, and I thought a valuation of $100 would be fair, because in fooling around with different properties and handling a lot of houses like that we usually get that much out of them. After going back to Fritch and looking the thing over I realized that when these projects are abandoned there will be a great migration away from the Panhandle. The dust storms up there have been very severe. It is in what they call the dust bowl of the Panhandle and Oklahoma, and people are not living there unless they have to, unless they are working for companies engaged in business there, except a few ranchers. The population of Hutchinson County, where Fritch is, I believe was 13 before oil was discovered, and I have been told that there was not a lawyer or a doctor in the whole county—just a couple of ranch houses. Certainly when these oil fields are abandoned, while the Panhandle will not revert to such a condition, I suppose it will be a pretty barren place, and just at the present time where these houses sit, who will want to buy them? I do not believe they are going to have much value, but I did suggest that value, and Mr. Davidson set it up in the record.

When I visited the Geneseo station, I noticed several of the towns were pretty empty. There were houses boarded up on the street, even large brick buildings boarded up, not being used. If that is an indication of the quality of the activity around there, I do not believe the houses will bring very much. Some of these cottages will probably be wanted by the farmers and by people who will want to move them to little towns. They are too large to move over the road very far, probably too large to pass over a bridge or something of that kind, but some of them will have some salvage value. From the portion of the set-up
I have been, this value of $100 per house is high, but
885 probably is somewhere in line, taking the other stations
which I have not seen into account.

I heard Mr. Taubman testify about this main line and this main gathering pipe, which is 24-inch dimension pipe, and these 18-inch, 16-inch, 12-inch, and 10-inch river lines, 6-run, 2-run, 3-run, and 5-run headers, and 24-inch and other dimensions of flanged gate valves which are used on this large diameter pipe and which are down below the ground with that pipe. We have bought a good many pipelines. We have bought them in a good many places, such as Wyoming, Colorado, and all the states of the Mid-Continent, but we never bought a 24-inch pipeline. None have been offered, and if there had been one offered, I do not believe we would have bought it. Oftentimes in effecting a salvage deal you just cannot afford to buy it because there is no value there.

The function of the dealer in used material is to find materials which can be reconditioned and used in the economic system and be sold advantageously. This 24-inch line is absolutely worthless. There would be no market for it if it was salvaged, and if it had to be junked, the cost of shipping it to the junk market would greatly exceed any possible revenue that could be had for it. I heard Mr. Taubman's statement that in his judgment it would take $15 a ton to remove it from the ditch and to go through all the steps which I heard him discuss and get it to the railroad. I am in accord with his estimate except that I seriously doubt that it could be done for that sum of money. That is the minimum.

In a break-down of figures on which his estimate was based and which he went over there was, for example, a charge for ditching that line of 10 cents per foot. That line is buried to an average depth, I believe, of 59 inches to where the top of the line is, and it would have to be uncovered one-third below that. I do not believe you could go up and down the line and ditch it for 10 cents a foot. I suggest that figure as low. The river crossings and headers used in connection with them could not possibly be salvaged. The cost of salvaging would be more than it is worth. In most cases you could not salvage it even if you wanted to. You do not know where the lines have shifted in the beds of the streams. It would be like looking for a needle in a haystack to find those lines across these river beds. It just could not be done, and there is no question in my mind about that.

As to the water well equipment, such as motors and pumps, set out on Page 22 and some other pages of this exhibit, we have handled a good many motors in our experience in our purchase of other second-hand material. With reference to these Layne Western pumps, we have never bought or sold any of those pumps. I only know from my observation that it is very good equipment, equipment of that nature.

There is a salvage value of 10% of the original cost of those motors set up in the exhibit, and the salvage value on the following page of 10% on the original cost of motors acquired after June 1, 1939, is set up. I believe that is a proper value and reasonable and in line with the used material market. Certainly that is the most that we could offer for that class of material if it were offered to us.

With reference to the pumps, I guess I was the one who suggested to Mr. Davidson this 10% valuation. I
886 probably did not think enough about the use of those
pumps and the conditions under which they were used when I suggested it. There is a possibility that some of them could be sold, but when Mr. Smith and I went out to the Panhandle and I talked to him he told me very emphatically that those pumps had no value and that we should not have suggested any value for them. I think I would have to acknowledge that it was an error on my part in placing a value on them. I am convinced that they are junk. It would not pay to take them out of the wells and put them on top of the ground and junk them. They should be left where they are in the wells.

Listed in this Exhibit 122 is a large variety of property listed under the caption of "Tools." The lists appear on pages 43 to 47 and pages 87, 88, and 89. As to this type of equipment, every time you buy used material the object of the seller is to get you to take as much miscellaneous material of this kind off the hands of the seller as possible. We have had to take quite a lot of similar material, although probably not identical. The salvage value as set up in this report is 10% of the original cost. Frankly, all of this material could not be sold by any dealer anywhere. There are some items that a dealer would keep forever and not find any way to dispose of or anybody that wanted them. A lot of it is special equipment ordered particularly for this system. Some of the items you would get a little more for because they are more commonly used than others. I still think 10% of the original cost of this material is a large and fair valuation to place upon it for salvage.

There is another miscellaneous grouping of equipment under the title "Miscellaneous Equipment—Account 1006-J," appearing on pages 32, 33, 67, 68, 78, and 79. I am familiar with most of that equipment. Naturally, in any list of that kind there are going to be some special items that nobody is familiar with who did not order them. However, I believe what I said about the tools is also true of this material in its entirety, except this: If you can conceive of a second-hand dealer having all this material in his stock, you cannot conceive of the buyer of most of this type of equipment going to any second-hand dealer to get this stuff, those specialized tools. If the dealer was in Houston, the use for them might be somewhere else in the country. It is small stuff. It would be hard to transport it, and even though there is 10% valuation placed on it, as to a great deal of it whoever gets it will never be able to dispose of it.

There are a number of different types of tanks appearing on page 27 and all through here. To save time I will classify them into tanks of what we call 450 gallons and down, or small tanks, and those 150,000 and 200,000 gallon elevated tanks built on the Fritch station and other stations. Tanks that are 15 or 20 years old will be in pretty bad shape. I do not believe there is much resale or salvage value to them. Just the other day I bought for our company three wells in Talco, Texas, and in connection with those wells we salvaged some tanks, two 500 barrel tanks, a 1,000 barrel tank, and one smaller tank. Now those tanks were only in use at Talco for about a year and a half, and yet when we examined them the bottoms were rotted out, and we sold them in place to a dealer in used tanks for about 5 or 6 per cent of what they originally cost. We were glad to get rid of them. Now we are dealing in tanks 15 or 20 years old, so I think the 5 per cent valuation set up here is very reasonable. I want to call attention to the 887 fact that a good deal of the cost of a tank is the cost of putting it up on the location where it is. The steel or material is not the only substantial item in the value of the average tank. A good deal of the value of it is building it, erecting it, and so forth.

These large 100,000 and 200,000-gallon tanks are elevated tanks, and they just have to be cut up. After they are cut up it will be a very difficult matter to rebuild them again. I do not believe it would be worth while contemplating that. I would sell those for scrap. Even a large tank, such as a 55,000-barrel tank, has a great deal of steel in it, and it only has a salvage value in the oil industry of five or six hundred dollars, and there have been hundreds of them sold over the past ten years at prices within that range. ~~The small tanks are riveted also~~, but they can be hauled on trucks and carried away. They would not have to be cut up and re-riveted.

As to the laboratory equipment appearing in Account 1014 on pages 40 and 90, I noticed that there has been a salvage value of 20% given to that. This laboratory equipment includes a number of special items, and good items, that have been purchased for the system. I believe they will keep this laboratory up in full notch order to the last minute, so they should have a higher salvage value than other classifications. Our organization in the last two years has equipped two or three refinery laboratories complete. In equipping such a laboratory we will issue purchase orders to 25 or 30 different manufacturers of laboratory equipment, and assemble this equipment, and sell it, and I believe you could sell this equipment, or most of it, although again some items might be hard to dispose of or perhaps might never be disposed of.

I believe the 20% figure is reasonable and proper as to the engines listed in Account No. 1024 on pages 92 and 93. There is one of them installed now, and Mr. Smith and I when at Fritch drove out there and looked at that engine. It is a combination engine and compressor cylinder used to increase the pressure from the gas wells to assist in boosting the gas into the line. I believe they contemplate, as the well pressures go down, installing these at different wells for the same purpose.

All through the country a 40 horsepower vertical gas engine is used for pumping oil wells, in connection with the power plants which pump oil wells, and are generally that size, so I believe those engines, if they are salvaged, could possibly be used throughout the oil country. We will always buy 40 horsepower engines. Usually these engines are three to five years old. Sometimes they are ten years old. They are seldom older than that. We pay prices ranging from $200 to $250 or $300 for these engines, depending on the condition of them, the manufacturer, the location of them, and how much it will cost to fix them up to resell them. So I believe the price of $200, or 10%, which we have placed on these engines, which is a little over $200, is a reasonable price and is in line with the salvage value of this type of equipment. Inasmuch as this is a new thing, none of these engines have ever been salvaged before. I believe this is the first one that was ever made.

Referring to the warehouse stocks, such as are listed on page 94 through page 102, consisting of engine parts, pipes, and fittings, casing, couplings, gate valves, and similar material, this is the type of equipment that I ordinarily deal in. That is, a good deal of it is. In contemplating
888 the salvage of this system we included in our calculations of pipe less than 12 inches in size the valves and fittings of this pipe and such valves and fittings as were

in these warehouse stocks. The only different factor is the cost of reclaiming. There will be no cost of reclaiming when it is in the warehouse stocks. It just has to be loaded with the other material into cars. That is true with reference to the Worthington engine parts. Since there is no market for these engines and they will have to be junked, naturally those parts for such engines would similarly have no value and should be sent up to the scrap heap.

As to the material other than engine parts, we have given the same value to that material that we have given to the reclaimed equipment of the same character, which is $20 a ton. All the material in the warehouse stock is not new and will not be new. They take new material out and bring material in from other uses when they are through with it, and a lot of that material in the warehouse stocks is second-hand material or material they had taken and cleaned up and put in the warehouse with a view of using it again if the occasion requires.

I have had experience in dealing with the type of equipment referred to in Exhibit 122 as cleaning tools. Our concern at one time made, and still has the facilities to manufacture, a complete line of cable tools, which these are. If we had a sufficient market we would manufacture these tools today. We still make certain cable tool specialties, such as Crotto wire line clamps, the Hardenberg underreamers, and other tools. The market for tools of this kind has been gradually disappearing over the last ten years. I guess in our own stocks we have between $200,000 and $300,000 worth of new tools that we would be happy to dispose of at 10% of their original sales price, or possibly less. However, in certain parts of the oil country, such as the Panhandle, there is still a small demand and a small use for cleaning out tools, and they are bought and sold.

After the wells are drilled, usually with the rotary method, if you want to go back in them, you employ a drilling contractor with a drilling machine or a spudder to go in there and clean out the wells, because it is too expensive to go into these holes with heavy rotary equipment. In the Wichita Falls area after we drill the holes out with rotaries, we drill them with spudders, so there is a small value to these tools. Remember this, however, that it is expensive to mishandle and to have trouble with tools. Tools that are 15 or 20 years old would be a very serious matter to use, and a prudent contractor would hesitate very much to consider putting them into a well. Of course, there are certain minor improvements in the building and construction of this equipment. I think the 10% valuation which I myself placed on these tools is pretty liberal.

I have had experience in trying to dispose of material of this kind which has been accumulated on a rather large scale. At Pampa alone we have had months where we sold as much as $250,000 to $300,000 worth of used equipment. We have made sizeable used material deals. Several years ago we bought all the lapweld casing and line pipe that the Midwest Refining Company had in Colorado, Utah, and Wyoming. While I was up in that country Mr. Wilson the vice president of the Texas Company, got hold of me and asked me to inspect all their drilling equipment, 889 which they wanted to sell, as they were going out of the drilling business themselves and turning their work over to contractors. Their superintendent, Mr. Leo Daley, and I made a trip through Colorado and Wyoming to every one of their properties, the Florence, Isle Dome, and other points, and I looked at a group of tools which had an inventory value of almost $800,000. After I figured the freight on these tools back to the Mid-Continent field I had to inform the Texas Company that in my judgment they had no value at all, and I could not use them. I could not recommend anything for them. It is my understanding that they finally sold them to a junk dealer in Casper, Wyoming.

I have had experience in cleaning up plant sites after the salvage of the material such as buildings, engine units, tanks, and other above-foundation property have been removed. Oftentimes we have had to clean up leases when we left them. After I joined the Western Supply Company I bought a number of refineries personally. You remember the Oklahoma Petroleum and Gasoline Company that had a plant at Dual. I junked that plant myself, and we bought gasoline plants and junked them, and we built gasoline plants. We have had a lot of experience generally with that kind of work. Frankly, I think the minimum cost estimates shown in Exhibit 122 of $3600 in the case of all these plant sites, with the exception of Fritch, in which the figure is shown at more than $10,000, are very reasonable for cleaning up and conditioning these sites. I caused the auditors over there to do a lot of work. I asked them how much concrete was put into the foundations and pits in those nine compressor stations and at Fritch. In answer they gave me, without adding it all up, the figure of over 42,000 yards. That just gives you an idea of the immense amount of these foundations, these concrete pillars, these concrete wall pits, and everything of that kind.

Now those plants today are just as clean as a whistle. There is no place in the oil country where any property is any cleaner or better kept than those compressor stations. There is no pin loose in it. There are no loose amounts of dirt or anything of that kind. I believe honestly that if I were offered the opportunity to clean those sites up for what Mr. Davidson has estimated it would cost, I certainly would not undertake to do it. I think the figure is very low.

You can't go off and leave those sites instead of cleaning them up and by that means save $3600. It would be a very dangerous thing for an individual or a corporation or anybody else to abandon a property that has deep pits in it which would be filled with water where people and cattle would drown, with walls sticking up all over among the weeds where people would drive down the country lanes and run into them. There is danger of that and other things that could happen, and anybody who is acquainted with the oil country knows these things could happen when you give the least opportunity for them to occur.

The prevailing custom throughout the oil and gas country is to clean up and level off these plant sites. If we buy a plant from any company, they will put in their contract an obligation for us to clean that off satisfactorily to the customer. You remember I mentioned a few moments ago we bought a few wells a couple of weeks ago at Talco, Texas. These three wells had three derricks sitting over them. Each derrick stands on four concrete posts about 4½ feet high. The city of Talco made us level those posts off, and we had to contract to have that done
890 before we abandoned those walls and pay the contractor so they knew the job would be done. Now anywhere in the oil country, whether you have to or not, you want to do that because you would not want to leave yourself wide open to all kinds of damage suits or lawsuits, even if you were not afraid of them and were protected by insurance. You would not want to leave a nuisance which would cause some innocent person to be injured or hurt in any way.

I spoke earlier about leaving the pumps in the bottom of the water wells. The wells themselves should be filled up and plugged, just like all the other wells in the system, for the same reasons that I have given with reference to pits. We cannot leave holes in the ground.

I have seen the list submitted to the Examiner this morning by Mr. Davidson of property which is not included in Exhibit 122 and which is not covered by his testimony in connection with that exhibit. He has described the property under the caption: "Non-salvageable property not listed in Exhibit 122." That covers such items as the telephone system, right-of-way easements, and various items that are set on those four pages. A great deal of it has to do with concrete work, concrete anchors, pipe racks, engine and building foundations.

When I first went to Chicago Mr. Davidson and I went over the entire property inventories of defendants. It was a tedious task, and it took several days to just go through it, and there are a number of items, principally these items here, that I would say have no possible salvage value of any kind whatsoever. He would jot them off, so I am probably responsible for a good many of these items being left out of the other exhibit. They are just worthless from any point of view whatsoever that I could figure out. Take the item of 28-inch highway and railroad crossing casing, which Mr. Davidson has testified would have to be taken out from under the railroad company's right-of-way easement. If all that pipe was at any one place, it could be loaded out, like this other pipe we have discussed, on a $20 per ton basis. That much could be salvaged out of the cost of getting it out of the ditches, but since it is scattered up and down the system, it would cost more than that to assemble it in carload lots at these various points, so it is just worthless.

As to the cooling towers, the Bentube sections have been salvaged, the pits under the towers are being filled up. What we are talking about now is a wooden structure. That is only good for kindling wood, if it has dried up enough to be used for that. It is just a series of wood slats that have had water running over them for years. We could not attempt to use them on new installation or anything of that kind. In my judgment there is no salvage value in any of the material listed on those pages.

Cross-Examination by Mr. Slaff.

I have never testified in any case on matters similar to those matters on which I am now testifying.

891 Cross-Examination by Mr. Booth:

My study of the salvage value, and the salvage values which I have attributed to material, are based upon such values as they exist in 1939. I have given no consideration at all or made any endeavor to arrive at any conclusions as to conditions which might prevail in 1954, except to that extent that in the used material business you are always handling material that is old. You get material offered to you that is 15 years old, 20 years old, 10 years old, or 25 years old. I mean you are always dealing with equipment of that age, and I believe it is reasonable to assume in dealing with equipment of that age that it is just about like it was 10 years ago, or just about like it will be 10 years from now. I make no effort to predict what the material will be worth 10 years from now. My conclusions are predicated upon conditions which prevail in 1939, and I have made no study or made no estimate of conditions which will prevail in 1954, fifteen years from now, except that in dealing with used material you are always dealing in material that is 15 years old, and it is reasonable to suppose that 15 years ago you were doing that, and if you were doing it then, it is reasonable to suppose that you will continue to do that and that similar conditions will prevail. There are, of course, exceptional conditions which can occur, but I do not attempt to be a prophet. I am not stating now that the conditions with respect to the sale of the properties of these two companies in 1954 will be identical with the conditions which exist in 1939. I am in no position to predict, nor do I endeavor to predict the conditions which will prevail in 1954. All I was asked by Mr. Morgan to do was to determine the salvage value of these properties and this equipment based upon conditions which exist in 1939.

Questions by the Examiner.

The corrugated iron tool house and garage at Kingsmill is not a structural steel building but just a small oil field tool house like a great many on that system. We have one of them of our own, I guess, two miles from there in the

Panhandle, that has absolutely no value whatever. This little water well house is just a tin-covered house over the water well. You would not haul it away for all the material in it.

Redirect Examination by Mr. Morgan.

They have those little tool houses with corrugated iron nailed to wood frame structures. We have them in that immediate vicinity not two miles from there. They are just built of two-by-fours with corrugated iron nailed on them to put tools into. They have no value at all when you build them and certainly are not worth anything when you salvage them.

892 HERMAN P. TAUBMAN, recalled for cross-examination, testified:

Cross-Examination by Mr. Booth.

(August 30, 1939.)

My estimate of the salvage value of the property of these two companies was based entirely upon conditions which prevail in 1939. I did not, and was not asked to, predict the conditions which will prevail in 1954. I would not call it unreasonable, if I were asked to predict the conditions which might prevail in 1954 effecting the salvage value of this property, because you have got always to figure back based on a certain age. I do not profess to know what will happen in the future. I do not know the business conditions which will prevail in 1954, which is obviously one of the factors and an important factor which would have to be considered in arriving at the salvage value of this property.

All I was asked to do was to determine the salvage value of certain equipment and property of these two companies on the assumption that the property was approximately 20 years old and based on the salvage market value conditions in 1939.

893 (August 31, 1939.)

(EXHIBIT 122 for identification was offered and received in evidence over the objection of counsel for complainant and counsel for the Commission, who were granted exceptions.)

894 F. C. HAMILTON, a witness for the defendants, testified as follows:

Direct Examination by Mr. Morgan.

(August 31, 1939.)

My name is F. C. Hamilton. I live in East Orange, New Jersey. My place of business is at Sixty Wall Tower, New York City. I am a consulting engineer engaged in making valuations of public utilities and natural gas pipelines for various purposes. At the present time I am consulting engineer for Electric Advisers, Incorporated. My time for that corporation is devoted to valuation work although that organization is not devoted to that type of work.

I have been engaged in valuation work since July, 1914. From July, 1914, to April, 1917, I was employed by Harold Almert in the Rookery Building in Chicago. During that period two of the principal valuations on which I worked were the Washington Railway and Electric Company in the District of Columbia and the Commonwealth Edison Company in Chicago.

From April 1, 1917, until October 1, 1935, I was employed as a consulting engineer by Henry L. Doherty and Company, who were employed by the Cities Service Company to supervise operations of the subsidiaries of the Cities Service Company.

From October 1, 1935, to December 31, 1937, I was employed by the Cities Service Company directly, and from January 1, 1938 to date by the Electric Advisers, Incorporated.

The valuations with which I have been connected were of natural gas pipelines, utility properties and oil properties for the purpose of purchase or sale, and valuations of natural gas pipeline and utility properties for the purpose of establishing rate bases before courts and public utility commissions and some city councils. There were valuations for the purpose of presentation before state commissions and later the Securities and Exchange Commission in connection with the issuance of securities. There were valuations for insurance purposes and for tax purposes. There were valuations for presentation to bond houses and insurance companies having to do with the sale of securities.

At all times during my employment above outlined I have been at liberty and have received employment from companies other than Cities Service and its subsidiary companies. Electric Advisers, Incorporated, is owned by the subsidiary companies of Cities Service and is a purely service at cost organization, so far as those companies are concerned.

Some of the companies for whom I have prepared valuations or rendered valuation services outside of my own organization are Columbus Gas and Fuel Company in Columbus, Ohio, The Iroquois Natural Gas Company at Buffalo, the Calgary Gas Company at Calgary, Canada, the Federal Gas and Fuel Company at Columbus, Ohio, the United Fuel Gas Company at Charleston, West Virginia, the Pennsylvania Gas Company at Erie, Pennsylvania, the Jamaica Water Company at New York, the receiver 895 for the Kansas Natural Gas Company under Judge Booth at the time that company was in receivership, and many others.

I have appeared before commissions, municipal councils, and courts in connection with these valuations in about 22 states, namely: Connecticut, New York, Pennsylvania, Maryland, North Carolina, Virginia, Texas, Georgia, Alabama, Mississippi, Arkansas, Tennessee, Oklahoma, Kansas, Missouri, Colorado, Wyoming, Washington, Minnesota, Illinois, Ohio, Michigan, District of Columbia, and the provinces of Alberta and Ontario, Canada. The amount involved in these various valuations was considerably in excess of two billion dollars in the aggregate.

During that period there were purchased through negotiations which I have conducted 37 properties on which I fixed valuations, totaling $165,000,000. During that same period I valued properties which were not purchased, because of failure to meet on prices, in the amount of $95,000,000. I have made valuations for the purpose of conducting negotiations for the sale of 23 utility properties with a total value of approximately $60,000,000. During the same period I conducted successful negotiations for the purchase of 29 oil properties with a total value of $53,000,000, and conducted negotiations in connection with other oil properties which were not purchased to the number of 34, with the total value of $106,000,000

Those were negotiations for purchase and sale. In those transactions I had the responsibility of arriving at the value for the interest I represented, and those I represented relied on my judgment a great portion of the time as to whether or not they would purchase or sell the property so far as its valuation was concerned. They have relied upon my judgment a great portion of the time except that in the 1927 and 1928 boom I advocated the sale of some properties, and they disagreed with me.

A very large portion in total number of dollars falls under the classification for the establishment of rate bases of various properties, and another considerable portion under the classification of establishing a value for the issuance of securities and/or the sale of those securities.

I have had a considerable organization throughout the whole period, varying in number of men from 15 to a high of about 75. As I recall it, there are about 55 men in the organization now. Some of them have been with me for as much as 22 years, and the average of the nine top men is in excess of 15 years. The force is almost entirely made up of graduate engineers from the leading colleges, who have had experience in natural gas pipelines or on utility properties prior to coming with me. I consider that this organization and force which I utilized in these studies is composed of men competent to perform the duties to which they are assigned. I have been completely cold-blooded in weeding out people who were inaccurate, unwilling to devote their entire energy to the work, and who seemed to me to lack the mental ability.

I have been going back with valuations to the same commissions over and over again, many times for the same clients, and that is something that cannot be done with a force that is either careless or inaccurate in this work.

896 For use in the valuation of a property such as that of a natural gas pipeline I have prepared myself with factual data concerning what is involved in the construction of a property of that kind. For years it has been my practice on new pipeline construction jobs, whether they were being conducted by contractors or by the Cities Service Company or by the forces of other companies, to put men on those jobs to follow the construction from the beginning to the completion of the work. They have kept the time of the men and gangs by the units of work which those men or gangs were doing. By that I mean a gang for trenching, a gang for backfill, and so on. Those hours were so kept that they would, at the labor rates then prevailing, balance out with the payroll that was being kept on the job.

I wanted that for the purpose of establishing the man hours that were necessary to do a specific piece of work, so that, with those man hours and with that gang set-up I could, at a later date, apply a changed labor schedule that might then be in force and arrive at what would be the cost of reconstructing that pipeline at a period when prices had changed. I incurred the expense of doing this work and I never was recompensed for that work at all, except in the sense that on later jobs I had available for my use accurate information, and my recompense came in the fact that it secured me employment because of the accuracy of the data. That was an expense and a means which I incurred and adopted as a preparation for the work that I am holding myself out to do.

As an incident to learning the number of man hours required to install a given unit there was kept the original cost of the equipment, the type of the equipment, and the gasoline and oil consumption where they used gasoline and oil, and the maintenance cost.

I made and kept a record of this character on the work on Natural Gas Pipeline Company of America and Texoma Natural Gas Company. At the time this line was constructed it was the largest line constructed as a single unit up to that time, and I wanted to and did get time studies on that line in great detail. I have used those time studies and the other information which I got in the same connection in the work concerning which I am about to testify.

In applying these man-hour costs, unit costs of that character, I have taken into account such changes as I have found in the character of the machinery employed or appliances employed—in other words, the technological changes that have occurred in connection with the construction of properties of this kind—because we are familiar with the changes that have been made in the equipment. I have made it my business to keep up with the changes that have been made. I am familiar with the relative man hours that are required and have given effect to those changes where they occur as the result of any technological improvements or advances.

I have been keeping this man-hour and similar type of study and records since about the year 1925. I have kept it up to the present time and am engaged in making out at the present minute on 40 miles of 8-inch line being laid southwest from Hutchinson, Kansas, to a gas field there. I have kept up that practice of sending men out to these construction jobs and getting studies of this character and have observed the records of them from 1925 to the present date.

897 I have been asked to make a valuation of the properties of the defendant. I was engaged to perform that service in February, 1938, and the work started about the first of March and continued to the 20th of August that year. In fixing the valuation I took a date certain as of January 1, 1938. There were employed on that work at that time 1894-1/2 man days.

That is not all the work we have done in that connection. Again in April, 1939, I was requested to bring that valuation down to date by the additions and betterments, that had been made in the meantime, the removal of such small items as had been retired, and bringing the valuation up to a date certain as of June 1, 1939. On this work there were 725 man days employed.

I was asked to value all of the physical properties with the exception of leases. In other words, I took the wells and well equipment on the leases but did not attempt to establish a value for the leases themselves. I took all other physical property, pipelines, compressor stations, buildings, and so on, and did establish first the cost of reproduction of those physical units without including anything except the costs of the inert property at the time of completion before it had been seasoned and before it had business attached to it.

I had access to the books and records of the companies but did not attempt to establish the original cost of the property, but I did use those books and records as checks on the inventory as to quantities. We were not told by the management of these companies at the time we were asked to place values on these properties, with the exception of leases, as to the methods we would pursue in arriving at the values. Our task was to arrive at the value by such means as we, with the training and experience that we had, saw fit to use.

I started first with the cost of reproduction of the physical property, including those items of interest, taxes, and other necessary costs during construction that are sometimes called overhead, but which are just as necessary as the labor of the man who digs the ditch. I then, on completion of this, deducted from that cost of reproduction the observed depreciation which was prepared by P. McDonald Biddison. I took the figures for existing depreciation on the present properties and applied them to the cost of reproduction and by that means arrived at my conception of present value. That is the method of arriving at present value that I have always employed in connection with the valuation work which I have done throughout all these years.

In addition to ascertaining the cost of reproducing the inert physical properties, including the overhead charges of various kinds which I have mentioned, I, at the request of these companies, have also undertaken to develop the going concern value of the property as separate and distinct from physical property itself. In that connection I have worked out the necessary working capital that must be employed in a business of the character and magnitude of these pipelines. All of those are included in the studies which we are prepared to present to the Examiner.

898 When we were employed to undertake this study back in February, 1938, I assigned Mr. H. L. Eastman, Mr. J. L. Willard, and Mr. Frank Stoddart to supervise the gathering of the information and the putting together of this information under my direction. These men were all experienced and had been with me for many years. With that group went a large number of other men who worked under the direction of these three in the preparation of that valuation.

There were employed 21 men in the period from March to August, inclusive, in 1938, and 12 men in the period from May to August, inclusive, in 1939. These men have devoted a total of 2618 man days to this work.

To Mr. Eastman I assigned the establishing of the labor rates in the various sections as of a particular time and the establishing of the value of rights-of-way and of land, and the determination of the working capital and the overheads, such as interest, insurance, taxes during construction, etc.

To Mr. Willard was assigned the supervision of the inventory of the physical property other than the well equipment on the leases and other than the measuring stations. The inventory on those last items was assigned to Mr. Stoddart. There was assigned to Mr. Willard the build-up of the unit costs from the time studies and from the labor rates which would be supplied to him by Mr. Eastman. Other details they adjusted among themselves and assigned the necessary men to work out the details. The group that worked on this last job had an average of 11 years in my employ, and all of them had experience prior to coming with me.

As I have always done my work it goes into very great detail. I have prepared a detailed inventory of all of the existing physical properties of these pipelines with the exception of the gas leases. I have not only broken that down into units, but, for the purpose of pricing the units, have broken them up by districts many times because of the variation in freight rates, the variation in labor costs, and items of that kind.

There are so many different items, so many different sources of manufacture, so many delivery points, that a freight rate study is a very detailed proposition, and we have applied the present freight rates which, by the way, were changed from the rates in existence at the time of the 1938 valuation. I mean by that that in the interim freight rates have been raised 10%, as the papers refer to it. Of course, no individual rate was raised exactly 10%. The average raise was 10%, and we had to get the new specific freight rate that did apply in order to attach it to the particular item and to the particular delivery point to which this item had to be delivered.

The labor costs similarly had to be gone into in great detail because of a large variation. For instance, in the rates for common labor in the States of Texas and Oklahoma and the rate for the same common labor in the district around Chicago there is a large variation. In other words, there is a variation there of probably 80 or 90% that the rates in Chicago for the same item are above the rates in Texas.

899 We had to vary our prices by states, for instance, because of the difference in the taxes that apply to payrolls or the labor item, one state as against another, and because of the difference between, or the absence of, use and sales taxes for materials. Those are just samples of the detail to which it is necessary to go in order to get an accurate determination of what it would now cost to reproduce this property in its present location.

I have assembled the detail of these inventories and set out the cost of reproducing each unit of the physical property in the form of a volume or compilation to be offered as an exhibit in this case. I have kept up with the preparation of that exhibit and examined it and know what is in it. I have spent a lot of time on it myself.

(At this point the witness was handed two volumes numbered I and II respectively, each captioned "Valuation Natural Gas Pipeline Company of America, Texoma Natural

Gas Company, F. C. Hamilton, Consulting Engineer, New York, New York," and at the request of counsel for the defendants the Examiner directed that these volumes be marked for identification as Exhibit No. 125, Volume I and Volume II.)

These are the compilations which we have prepared as exhibits to be offered in this case.

Mr. Slaff: Then at this time I should like to object, Mr. Examiner, and to be heard on the objection to the introduction of any evidence dealing with the reproduction cost of the properties of the defendants-respondents on the ground that that evidence is irrelevant, immaterial, and incompetent in this proceeding, and on the ground that that evidence of reproduction cost has no bearing on the determination of the proper base for rate-making purposes in this case.

This is a proceeding under the Natural Gas Act, and I want to call the Examiner's attention specifically to Section 6 (a) of that Act which provides, in part, that "the Commission may investigate and ascertain the actual legitimate cost of the property of every natural gas company, the depreciation therein, and, when found necessary for rate-making purposes, other facts which bear on the determination of such cost or depreciation and the fair value of such property."

Now your Honor will observe that this is a legislative expression of a fundamental departure from previous rate-making concepts as they have existed in some quarters. In the first place, there is no statement in this section, or elsewhere in the act, that among the "other facts" to be investigated and ascertained which bear on the determination of "the fair value of such property" is the reproduction cost of such property. Now it is not an immutable constitutional concept that a determination of reproduction cost is a prerequisite to the determination of the fair value for rate-making purposes of utility property and the fixing of utility rates. I am fully aware, your Honor, of Smyth *vs.* Ames and the other decisions of the Supreme Court on utility matters, but it is quite clear to me, as the Supreme Court itself indicated in the term just past and in the preceding term in such cases as Graves *vs.* O'Keefe and Erie *vs.* Tompkins, that fundamental concepts of constitutional protection of property rights must be adjusted in the light of the economic experience of the nation.

Now I do not mean to imply at this time, or at any other time, that constitutional rights are to be subject to rapidly shifting vagaries and year-by-year changes, but I do mean that the Supreme Court itself has declared that when the progress of our complex economy has rendered obsolete or unworkable doctrines which had until that time been more or less accepted it was not in violation of but rather in keeping with the spirit of constitutional government that such doctrines be replaced by those which fit the needs of the modern age.

Now Congress recognized this in the passage of the Natural Gas Act and pointedly omitted to charge the Federal Power Commission with the duty of investigating and ascertaining the "reproduction cost" or the "replacement cost" of the property of natural gas companies, while specifically authorizing it to ascertain the actual legitimate cost of such property. Nor can it be successfully argued that this commission is charged with the duty of ascertaining reproduction cost under the doctrine of Smyth *vs.* Ames—ergo there was no need for congressional mandate—ergo the congressional omission is meaningless. That such argument falls of its own weight is at once obvious from the fact that, under Smyth *vs.* Ames, ascertainment of "actual legitimate cost" of the property,—there referred to as "the original cost of construction",—is also an element in the determination of fair value. Hence if Congress had intended to follow that case implicitly there would have been no necessity, either, for the explicit direction by Congress to the Commission to ascertain actual legitimate cost. The explicit inclusion of the one and the explicit exclusion of the other shows clearly that Congress recognized the inherent invalidity of reproduction cost determination as an aid to the process of fair rate-making. It is clear, therefore, that Congress, cognizant of the fact that the experience of years had shown that determination of reproduction cost had been perverted from an aid to an impediment in the determination of the rate base, clearly ruled that factor out of consideration by this Commission.

The Federal Power Commission is instructed by Congress to ascertain the "actual legitimate cost of the property of every natural gas company and its depreciation". There is no blanket instruction, no blanket direction similar to this one to go into "other facts" bearing on the fair value of such property. It is only in certain limited cases, to-wit, "when found necessary for rate-making purposes" that the Commission is instructed to determine "other facts" bearing on the determination of fair value.

Now there has been no showing whatever that in this case it is necessary for rate-making purposes that this Commission ascertain such other facts as the reproduction cost of the defendants'-Respondents' properties for rate-making purposes. Nor can there properly be such a showing.

I think, speaking generally, it can be ascertained confidently that the insistence by utility companies upon the introduction of evidence dealing with reproduction cost and that major weight be attached to reproduction cost as against any other element of value in the determination of the rate base has consistently impeded the regulatory processes in the past. This Commission itself has said, "It has been the considered judgment of the great majority of the regulatory commissions that the use of reproduction cost is not a proper factor in the determination of a valuation." And further, "The general opinion of regulatory authorities who have passed upon the question of the proper valuation base is overwhelmingly in favor of the prudent investment as opposed to the reproduction cost method."

The opinion of Commission counsel in this respect is expressed in the concurring opinion written by Mr. Justice Frankfurter for himself and Mr. Justice Black in the case of Driscoll *vs.* Edison in the term just passed that "the force of reason, confirmed by events, has gradually been rendering that formula (of Smyth *vs.* Ames) moribund by revealing it to be useless as a guide for adjudication. Experience has made it overwhelmingly clear that Smith *vs.* Ames and the uses to which it has been put represented an attempt to erect temporary facts into legal absolutes. The determination of utility rates—what may fairly be exacted from the public and what is adequate to increase enterprise—does not present questions of an essentially legal matter in the sense that legal education and lawyer's learning afford peculiar competence for their adjustment. These are matters for the application of whatever knowledge economics and finance may bring to the practicalities of business enterprise."

Congress, in the Natural Gas Act, has clearly indicated its intention to have the Federal Power Commission depart from that moribund formula of Smyth against Ames. In the light of that circumstance, there is no justification whatever for the introduction of reproduction cost evidence in this case.

Let me add, too, that Commission counsel is in wholehearted agreement with the fundamental principle of utility regulation which Mr. Justice Black very trenchantly expressed in his opinion in the McCart case, McCart against Indianapolis Water Company, 302 U. S., when he said:

"I do not believe that the constitutionality of action by a soverign state of this Union (or, I might add parenthetically, as in this case, 'the Union itself') is dependent upon the market fluctuations of cast iron pipe."

How particularly apt is that statement in the light of the very facts of this case where one of the major portions of the companies' investment is in just that very thing.

Moreover, Mr. Examiner, even if there were no such explicit expression of legislative intention as designated in the Natural Gas Act, and even if it were not for the fact that reproduction cost estimates have no sound place at all in the determination of a base for rate-making purposes, this case would fall squarely within the special type of situation covered in the Clark's Ferry Bridge Company case in 291 U. S., where Chief Justice Hughes wrote the opinion for a unanimous court. And in that case the court said:

"Appellant attacks the finding of fair value upon the ground that it was based solely on the original cost of the bridge property and that the amount paid by the appellant for the bridge was less than its fair value at that time and less than its fair value in 1930. It is not open to question that the reasonable cost of the bridge is good evidence of its value at the time of construction. And we have said 'such actual cost will continue fairly well to measure the amounts to be attributed to the physical elements of the property so long as there is no change in the level of applicable prices.' "

Now note particularly two things: first, that the Commission in the Clark's Ferry Bridge case took as the value of the utility the cost of its construction some seven years before the date at which the Commission fixed a fair value; and second, that the evidence introduced by the defendants-respondents in this very case establishes on its face that there is no change in the level of applicable prices, and that consequently the value of the properties in this case must be measured by, and only by, the actual legitimate cost of those properties, less depreciation.

Let me call your Honor's attention to Exhibit No. 67, which was introduced on behalf of the defendants-respondents by the Witness Palyi. Now, if your Honor will examine the indices on that exhibit you will note three that are particular pertinent to this discussion. First, is the companies' wage index. The Witness Palyi testified that this index was constructed by him as follows:

"From 1931 on we used the companies' own wage index, for which I had figures from the middle of 1931 until and into 1938. That index is a weighted, composite index of two indices, one for skilled labor used by the company and one for unskilled labor. Out of the two, by weighting in accordance with the annual expenditures in each category, skilled and unskilled, I constructed this one index number, which appears as the companies' wage index."

Now if your Honor will observe that exhibit and the witness' testimony, those wage expenditures were supposed to represent actual wages paid by the company to employees, and your Honor will observe that the company's wage index is at the latest date shown on Exhibit 67 lower than in 1931 at the completion of the construction of the company's property.

So, too, the second applicable index, the general price level index shown on that Exhibit 67, is lower at the beginning of 1939 than the average for the same general price level index during the period of construction of the properties of this company.

I call your Honor's attention to the fact that the Witness Palyi testified as follows:

"That is a very important aspect of the comparison; that the data for the history of the company covers only a short period. But I still say my impression of this price study is that there is a fair correspondence in the general trend in prices of commodities used by the company and in the general trend of what is called the general price levels in the country. This is, of course, theoretically obvious.

"If you spend money on these different types of commodities ranging from office supplies to storage batteries, from red lead to lumber, pipe, fittings, building materials, you cover so many things, as I mentioned yesterday, that, a priori, it would be most astonishing if your index number of prices fluctuated—would be very different in trend from the general index number, which would need an explanation if major differences for any length of time would occur; but that the trend is about the same, as a matter of fact, ought to be a priori, more or less obvious."

I stated a moment ago that the general price level index on Exhibit 67 is shown to be lower at the beginning of 1939 than the average for that index for the period of construction of the defendants-respondents' properties. Carrying that price trend down to the latest available date—a fact of which your Honor can now take judicial notice when it is, as now, called to your attention in open hearing—carrying that price trend down to the latest available date, we find that it is even still lower than shown on Exhibit 67. Projected down to the beginning of June, 1939, the general price level index would show, on Exhibit No. 67, as a figure of approximately 118 for the month of May, 1939. This compares with the figure of 126 shown for the end of the year 1938, and with the average figure of approximately 136 for the period shown as the companies' period of construction in 1930 and 1931.

We now come to the third of the companies' indices which has significance in this discussion, to wit, the "Index of Prices for Commodities Used by Natural Gas Pipeline Company of America", which also appears on Exhibit 67.

Even had there been no explicit statement to that effect in the record, we would be justified in assuming that these commodities were representative of the trend of prices generally of all commodities used by the companies. Now that index, as of the latest date shown on Exhibit 67, namely approximately the middle of 1938, is just approximately where it was during the period of construction of the companies' properties and has begun a downward swing. And if we accept at its face value the statement of the companies' witness Palyi that "there is a fair correspondence in the general trend of prices of commodities used by the company and in the general trend of what is called the general price levels in the country", then, of necessity, the index of prices for commodities used by the company must be even lower today than is shown at the latest date on Exhibit 67.

Now, I take it, Mr. Examiner, that it is not this Commission's intention to penalize investors by the fact that prices at the time the Commission fixes rates may be lower than they were at the time of original construction; although as I have pointed out a moment ago, there has been a drop in the general price level of approximately 13 percent from the time of the construction of the companies' properties to the present, I do not feel that the investors in this project should be penalized on this account. They are, as I view all the equities involved, and the constitutional requirements which are to be considered, here entitled to a fair return on the actual, legitimate cost, less depreciation, of the property now used and useful in the service of the public. Nor is it this Commission's intention, I take it, to penalize consumers when the converse of the facts which obtain in this case with respect to changes in price levels, is true.

And particularly, Mr. Examiner, when there has been little change in the applicable price levels and that change, if anything, has been to a point lower than the levels at the time of construction, I insist that the statement quoted from the Clark's Ferry Bridge case is applicable and that there is no necessity whatever that this Commission receive evidence of reproduction costs. For this hearing, and this Commission to engage in the incompetent mumbo jumbo, as it has been well called, of a reproduction cost estimate, would serve no purpose but to waste the time of everyone involved in this hearing and to delay the determination of the fairness of the rates of the defendants-respondents.

It seems to me, Mr. Examiner, that it is about time that this Gordian knot that has tied up the regulatory process for so long should finally be cut, and particularly is this true in the light of the fact that Congress has clearly expressed its intention that this be done in the regulation of natural gas companies.

Mr. Justice Stone aptly observed, in the concurring opinion in the St. Joseph Stockyards case, in 298 U. S., that, "the doctrine of stare decises, however appropriate and even necessary at times, has only a limited application in the field of constitutional law."

In the light of all these circumstances, Mr. Examiner, I must therefore object to the introduction in this proceeding of any evidence dealing with the matter of reproduction costs of the properties of the defendants-respondents, and I urge upon you that the rate base of the defendants-respondents be determined solely upon the basis of the actual legitimate cost of the properties, less depreciation, that is to say of those properties which are now used and useful in the service of the public, so that reasonable justice and speedy justice in the matter of rates may be done in this case on behalf of investors, consumers, and the public at large.

Mr. Booth: If the Examiner please, I would like to add a word or two before Judge Morgan answers the excellent argument that was made by counsel for the Federal Power Commission. I join in the objection for the reasons advanced by Mr. Slaff. I believe that this is an unusual proceeding. It is not like an ordinary rate case because, as Mr. Slaff has pointed out, there is a special statutory provision which I want to read again because it is brief:

"The Commission may investigate and ascertain the actual legitimate cost of the property of every natural gas company, the depreciation therein and, when found necessary for rate-making purposes, other facts which bear on the determination of such cost or depreciation and the fair value of such property."

It is obvious that that provision applies specifically to this proceeding. It seems to me that there must be a determination or at least a showing before evidence as to reproduction cost is introduced, that it is necessary in this proceeding that consideration be given to reproduction cost, and no evidence of that character has been offered. There has been no evidence that in the determination of the fair value of this property, it is necessary that the Commission give consideration to or find the reproduction cost of the companies' properties.

And furthermore, under the facts in this case and the exhibit, copy of which has just been handed to us and has been marked, it seems to me quite clear that no consideration is necessary or can reasonably be given to reproduction cost and value of property.

I raised the point earlier that the testimony which this Witness Hamilton had been giving was apparently of a misleading character because he apparently had made a reproduction cost study of the companies' property and he was calling it, and counsel for the company was calling it, the value of the property of the company.

Now, in the first place that is clearly contrary to the provisions of Section 6 (a); it is contrary to all the decisions of the court that say that in the determination of the value of the property of utility companies, generally speaking, consideration shall be given to original cost and if necessary to reproduction cost, or to both, under the individual facts in this case.

However, if you look at this exhibit you will note that on page 1 there is a reproduction cost new in the amount of $57,000,000, present value $54,000,000—the property is found to be at least in 95 percent condition. And that is the value of the companies' property.

Here is a property which, on the basis of the evidence submitted by the company has already operated for approximately 40 percent of its entire life, and yet, the company seeks to present evidence that in the determination of the rates to the consumers that the property shall be taken at 95 percent of its cost new, and that that is the sole element that shall be considered in the determination of the value of the property of the company.

Now it seems to be quite clear in my judgment that reproduction cost new under the facts in this case is not a necessary or a reasonable element because this is not an electric property, the company has presented evidence that the life of this property is going to expire in 12 more years, 10 more years. It must be clear that the reproduction cost new would be, upon the basis of the appraisal which the company is about to present, as high as the reproduction cost new which they have now submitted, if prices continue to maintain their present level between now and 1954, and their theory apparently, is that even though the property would have only a few more years of operation, that reproduction cost new, less observed depreciation, be taken as the sole element in the determination of value of the property of the company, and that, it seems to me, is highly unjustified.

Mr. Slaff also referred to the general experience of regulatory commissions which have been commented upon by the Federal Power Commission with reference to the use of reproduction cost. I agree with his viewpoint that the experience of utility commissions generally is that reproduction cost is an impediment and a very serious impediment to the prompt and fair determination of utility rates.

He referred to a number of court decisions. I would like to add one or two. There is a very recent decision of the Supreme Court of Wisconsin in the long litigated Wisconsin telephone rate case, which was handed down only within the last 30 or 40 days by the Supreme Court of Wisconsin, where the Supreme Court of Wisconsin criticised very severely the Wisconsin Commission for determining the rates of the Wisconsin Telephone Company on the basis of reproduction cost.

The trend of judicial decisions, the trend of Commission decisions, is very clearly away from the giving of consideration to reproduction cost in determining the fair value of the property. It seems clear, therefore, that the motion of counsel for the Federal Power Commission, in which we join, should be granted, that there should be no evidence as to reproduction cost submitted in this case, and the Commission under the specific provisions of Section 6-A should determine the value of the property on the basis of the actual legitimate cost, less depreciation, unless it is definitely shown that it is necessary that consideration be given to reproduction cost.

Mr. Morgan: May we take our recess at this time?

Examiner Simpson: Yes, we will have a five-minute recess.

(Thereupon a short recess was taken.)

Examiner Simpson: The hearing will resume.

Mr. Morgan: Mr. Examiner, I have been, as we all have, devoting myself to the study of the facts of this case for the past several months, and I am not prepared to go into a discussion of the authorities in the organized and learned manner in which counsel for the Power Commission has done, and in using those adjectives, I don't want to be understood as utilizing sarcasm or derision, because I think it is a very apt and a very splendid discussion of the subject from the point of view of that school of thought which has been advocating for some years a change in the law, a change as yet not effected, however.

Section 6-A of Natural Gas Act, as already stated, does mention that "the Commission may investigate and ascertain"—they don't have to but they "may investigate and ascertain the actual legitimate cost of the property of every natural gas company, the depreciation therein and, when found necessary for rate-making purposes, other facts which bear on the determination of such cost or depreciation and the fair value of such property."

They are not necessarily talking about rate-making purposes in the first part of that section at all. Now they get down to talk about rate-making purposes "and for rate-making purposes other facts", showing clearly that the Congress recognized that under the law as it was then being declared and had been declared since Smyth against Ames, that it was necessary to ascertain other facts in order to arrive at the fair value of the property which term they used here significantly, because that is what Smyth against Ames says, that it is the fair value of the property and not the original cost of it that must be given account in the matter of rate making.

Now there may have been Members of Congress who belonged to that school of thought which apparently Mr. Slaff and Mr. Booth subscribe to. By knowing something of the practical working of those things, I have some suspicion that somebody of that school of thought had something to do with the wording of Section 6. But the Congress, in enacting Section 6-A recognized that under certain circumstances it might be necessary to talk about other factors, and apparently one of the occasions when it might become necessary was when the Commission was investigating facts for rate-making purposes. There may have been Members of Congress who entertained the hope that the Supreme Court might, during the operation of this act, change the holding in Smyth against Ames and in the uniform line of majority opinions from that decision right on down to the present time, that it is necessary, in arriving at fair market value which the Supreme Court has uniformly held must be the rate base, to consider not only original cost but reproduction cost. They may have wanted to put the Federal Power Commission in a position so that if the Supreme Court held at any time during the operation of this act, that it was not necessary to consider anything but original cost, they might be in a position to do it. But unfortunately, from the standpoint of that school of thought, the Supreme Court has spoken again in the very case in which Justice Frankfurter wrote his dissenting opinion, and in that same dissent, Justice Frankfurter put this construction upon the majority opinion. He says that this court has reaffirmed the doctrine of Smyth against Ames, and that is the law, and I can't change it. This examiner can't change it. Mr. Slaff and Mr. Booth can't change it and nobody short of the Supreme Court of the United States can change it. I couldn't come here in the discharge of my responsibility to my clients and fail to present here evidence of reproduction costs which the courts have held, right down the line, must be considered in arriving at what the fair value of the property which the Congress itself calls the rate base in effect in Section No. 6-A is. And I can no more discharge my responsibility without bringing in here one of the necessary elements than I could if I didn't bring any evidence here at all.

Now Mr. Booth has taken pains to say that we are relying solely on reproduction costs. How does he know we are?

Mr. Booth: Your exhibit says valuation, and that is the reproduction cost appraisal.

Mr. Morgan: That is evidence of the value according to the testimony of the witnesses who are coming here to testify concerning these two volumes. But we haven't said we are relying solely upon it. As a matter of fact we are not. Yes—that is one of the things we are relying on. We say that the rate base is the fair value of the property, and we are bringing here evidence at this time of reproduction cost as evidence of the fair value of the property. Well, we will have other exhibits in which we will show the original cost and we are going to offer that ourselves as evidence of the present fair value of that property. This is just a part of our case, this is not all of it, and until we have rested, Mr. Booth is not at liberty, as I view it, to come here and say what we are relying on because we can't put all of this case in and state all of our positions at any one time.

Our position simply is this, that the rate base according to the doctrine of Smyth against Ames, which is still the law of the land, dealing with the constitutional rights of people, is the fair value of the property, and that the doctrine of the Supreme Court as announced in that case, and by the majority of the Court every time the matter has come up, is that in arriving at the fair value of the property, original cost must be considered and reproduction cost, less existing depreciation, must be considered.

We are trying to meet our responsibility under the law as it exists today because we can't change it, and we think that this would certainly be a record that would have to come back to the Commission if it went out of here without this evidence in it, and we are here prepared to present it and insist on the right to present it.

900 **H. L. EASTMAN**, a witness for the defendants, testified:

(August 31, 1939)

Direct Examination by Mr. Morgan.

My name is H. L. Eastman. I live in Maplewood, New Jersey. My place of business is at Sixty Wall Tower, New York City. I am associated with F. C. Hamilton, who preceded me on the witness stand. I have been employed by or associated with him, with the exception of a period of three years, since January, 1919.

I was graduated from the College of Engineering of the University of Colorado in 1917 with a degree of Bachelor of Science in electrical engineering. Immediately following my graduation I was employed by the Great Western Sugar Company, Scottsbluff, Nebraska, as a construction and later as an operating engineer. My employment with this company was terminated by the war when I entered the army.

While awaiting call to the army I took graduate work at the College of Engineering, University of Colorado, and completed the scholastic requirements for a Bachelor of Science degree in mechanical engineering. I spent the larger part of 1918 in the army.

Following my discharge from the army I was employed by F. C. Hamilton of New York City, who was then consulting engineer for Henry L. Doherty and Company. This was in January, 1919. In general I was engaged in the type of work already outlined by Mr. Hamilton in his testimony.

Upon my first employment with him I was assigned as a valuation engineer on valuations that were then under way. The largest property on the valuation of which I was employed during that two-year period, 1919 and 1920, was the property of the Toledo Edison Company in Toledo, Ohio. I was also employed on the valuation of the Durham Public Service Company of Durham, North Carolina and on a valuation which was being made for the receiver of the Kansas Natural Gas Company, involving property of that company and the Marnet Mining Company, a large natural gas system in Kansas, Oklahoma, and Missouri. I was also employed on valuations of the Wichita Natural Gas Company, the Quapaw Gas Company, the Webb City-

Carterville Gas Company, Carthage Gas Company, City Light and Traction Company, St. Joseph Railway Light, Heat, and Power Company, and some other smaller natural gas properties.

On January 1, 1921, I was employed by a group of natural gas properties which now comprise the Cities Service Gas Company of Bartlesville, Oklahoma, and I was employed by that group of properties as a valuation and rate engineer and on other general engineering problems. I remained with that group of companies until May, 1924, when I was again employed by Mr. Hamilton.

During that period of over three years I personally made detailed valuations of all of the natural gas properties operated from the Bartlesville office. I made studies of
901 rates for natural gas and assisted in various rate cases,
of which there were quite a number during this period, wherein the rates charged by these companies for natural gas were increased and the companies put on a profitable basis.

From May, 1924, to June, 1925, while in the employ of Mr. Hamilton, I resided in Kansas City, Missouri, and spent that year on general valuation and rate matters of natural gas properties and electric properties in that general vicinity.

In June, 1925, I moved to New Jersey, and since that date have been continuously associated with Mr. Hamilton. Until October 1 of 1935 we were consulting engineers for Henry L. Doherty and Company, fiscal agents for Cities Service Company. From October 1, 1935, until December 31, 1937, we were employed as consulting engineers for the Cities Service Company, and since January 1, 1938, have been associated with the Electric Advisers, Incorporated, a mutual service company. By mutual service company I refer to the type of mutual service company defined in the Public Utility Holding Company Act. I believe we are registered under Section 13 of that act.

Since 1925 I have been in active charge, through Mr. Hamilton, of an organization comprised of probably a minimum of 15 to a maximum of 75 men, who have been for the most part engaged in making valuations and rate analyses for public utility, natural gas, and in some cases petroleum properties. I have been associated with Mr. Hamilton in all of the valuation work done during the period on properties of which the total value will aggregate two billion dollars. Most of these properties were subsidiary companies of the Cities Service Company, and a large proportion were valued because of pending rate cases, for the purpose of security issues, or new financing.

We have also made numerous valuations of public utility, natural gas, and petroleum properties whose purchase was contemplated by the Cities Service Company or one of its subsidiaries. During this period from 1925 to date we have presented valuations before courts and commissions and other regulatory authorities in many different states, and I have personally appeared and testified before public utility commissions in the States of Oklahoma, Missouri, Texas, Kansas, Ohio, Michigan, Connecticut, and New York, and before the Interstate Commerce Commission and the Federal Power Commission. In addition I have participated in conferences over valuation and rate proceedings with public utility commissions in Colorado, Wyoming, Arkansas, Louisiana, Pennsylvania, New Mexico, Tennessee, North Carolina, and with the Securities and Exchange Commission.

Among the major properties which we have valued during this period from 1925 to date are the Toledo Edison Company, a major portion of the Ohio Public Service Company, the East Tennessee Light and Power Company, the Tennessee Eastern Electric Company, a large portion of the Public Service Company of Colorado, the Durham Public Service Company, the Empire District Electric Company, the St. Joseph Railway Light, Heat and Power Company, the City Light and Traction Company, the Knoxville Gas Company, the Spokane Gas and Fuel Company, the Republic Light, Heat and Power Company, the Dominion Natural Gas Company, Limited, the Southern Ontario Gas
Company, the Cities Service Gas Company, the Kan-
902 sas City Gas Company, the Ozark Utilities Company,
the Empire Pipeline Company, and many other properties whose purchase was contemplated and which we were requested to value.

In the Summer of 1930 I was sent to Western Canada to report on a contemplated natural gas pipeline project which had for its purpose the bringing of natural gas from the Turner Valley field in Alberta to the City of Winnepeg, Manitoba. In the Winter of 1930 and 1931 I was in charge of a survey of markets which contemplated the future marketing of natural gas, which it was hoped would be developed in large quantities in the Oriskany sand area of north central Pennsylvania and southwestern New York.

In the Fall of 1931 I made a complete detailed valuation of the Cities Service Gas Company for presentation to the Kansas Public Utilities Commission as a justification for the wholesale rates charged by this company. After presentation of this valuation and the other pertinent data this case was appealed to the United States District Court and eventually to the United States Supreme Court and was remanded back to the Commission for further findings. As a consequence we again made a detailed valuation of the Cities Service Gas Company in the Fall of 1934, and this was presented to the Kansas Commission during 1935. This case was later settled and disposed of by the Kansas Commission.

Since 1931 I have spent the greater portion of my time on the valuation of natural gas properties for presentation in rate cases before courts and commissions in the states of Kansas, Missouri, New York, Illinois, and in Washington, D. C..

I know about the record that Mr. Hamilton stated his organization had assembled and kept, and which he terms "time studies." I have quite a little to do with that study. We started this work as far back as 1925, and I have been quite familiar with each one of the studies that we have made since that time. The men actually engaged in the field in collecting and correlating the data were working directly under my supervision, and I familiar at all times with what they were doing. I have spent quite a good deal of time accompanying them in their work and endeavoring to see that the data which they collected was in the proper form and also to familiarize myself with construction methods.

We wanted this information for basic data and information which would be useful in making the valuation of similar property in the future. At the time the properties of defendants were being constructed we realized that here was the best opportunity that we had had up to that time to secure basic information of this sort on a large natural gas pipeline project, and we undertook to make time studies and collect data on representative sections of that line. We have had this data available and have used it in connection with the valuation studies that have been made by Mr. Hamilton and his organization, including myself, and which is now being presented to the Examiner.

I was among those first assigned by Mr. Hamilton to this particular study. After our arrival in Chicago, from which point the greater portion of our work was conducted, and the assembling of our men to carry on this work, the first step was the preparation of an inventory of the property.

Fortunately for us in this work, these companies were 903 constructed originally in almost their present form. That is, there have been very few additions to the property which we covered since the original construction. At the time of construction these companies kept a very adequate and detailed record of construction equipment and expenditures. They prepared a very excellent system of maps, and we made use of all this information which they had in their files in preparing the inventory of the property. When it came to the pipelines, we made use of their detailed pipeline maps, which showed the chainage notes, the pipes, and details of all special installations. Their other office records contained detailed plans, drawings, specifications dealing with the material, and we assembled all this data which we needed from their files and carefully analyzed them.

Then we sent field parties out to take inventory to the property in the field and to check the quantities of material which we had obtained from their regular records against the quantities as actually existed. We sent men to the Panhandle gas field who made inventories of the top fittings of the wells, casing, and checked the records of those wells. We sent men to the various compressor stations where they checked the quantities which they determined from the records of the company against the actual material at those stations. We sent men to the various compressor stations and structures along the line, and they made inventory of the cottages, dwellings, and other buildings, and we obtained lists of the construction tools which the company had, and the laboratory equipment, and other small items of that nature.

This data was assembled then and brought back to the office in Chicago and summarized and reduced to workable form. Quotations were then secured and unit prices evolved which would reflect the conditions as they existed on June 1, 1939. This inventory of which I spoke was a complete field inventory, where such type of inventory was necessary. On other portions of the property, where we knew of our own knowledge that they had an accurate inventory from regularly maintained records, it was more of a spot check. We, of course, could not see all of the joints of pipe that were in that pipeline, but we could see the engines and the buildings and those other things that are dealt with here as units. We actually inventoried the office equipment and furniture, mechanical equipment such as comptometers and adding machines, and all those things. We made a detailed list of all the physical property which went into these pipelines and which, when put together, constitute this pipeline system, with the exception of the gas leaseholds, which we did not include or value.

I was familiar with and supervised all of the work that was done. Personally I devoted a great deal of time to the appraisal of the real estate or land, the right-of-way, and to the calculation of certain costs which are detailed in the valuation and which we commonly refer to as general overhead. Also I made the calculations which were the basic data we used for working capital.

I did the field work which was necessary for the determination of the present schedule or levels of labor costs, and upon the completion of that work the various wage rates or wage levels which we have adopted and used
904 in this valuation were determined in conference with my associates.

For the most part the unit costs applied to the various units entering into the system were handled under Mr. Willard's direction. I kept up with it and kept advised as to how it was being done. I know what the results were from the exhibit which I helped prepare. I might state that in work of this kind it is absolutely impossible to delegate certain work to any one particular man. Most all of the work that is done is done by one or more men in collaboration. Calculations made by one man are checked by another, so that in a job of this kind probably three or four or five men are almost entirely familiar with everything that has gone into the finished report.

We determined what procedure would be necessary if this property were to be reproduced today, that is, the general method of construction. It was at once obvious that a pipeline system such as this would be constructed by general contractors. Companies of this character do not have a construction organization, and they never have a construction organization in the sense that they could construct and build themselves this entire property. So we undertook to determine from contractors who are engaged in building this particular kind of property the wage levels that prevailed as of June 1, 1939, and the wages they would have to pay were this property being constructed at that time. I personally visited the principal pipeline contractors and obtained from them the wage levels which they were paying at that time, which was June 1, 1939, in the territories traversed by this pipeline system, and of course these wage levels vary greatly throughout the territory covered by this system. They pay considerably more wages in some places up and down this pipeline than they do in other places. They pay more for hours of work. This pipeline traverses six states, and in the states of Texas, Oklahoma, Kansas, and Nebraska, and a portion of Iowa it could be constructed at the present time, I mean as of June 1, 1939, very largely with non-union labor. In the State of Illinois and in a considerable portion of the State of Iowa, however, union labor would have to be employed.

I do not mean that for all of the work, in most instances, non-union labor could be employed up to the central portion of Iowa and then union labor would have to be employed for all of the work east of that point, up to Joliet. The work of constructing the pipeline itself could be so done. The work of constructing the compressor stations, however, being of a different type and requiring a different type of skilled workman, is highly unionized, and all of the labor at compressor stations would be union labor, including that employed in the construction of housing facilities and other buildings. The work of constructing the pipeline across the State of Illinois would be solid union labor as would also be true of a portion of Iowa. This applies even to the common labor employed in the handling of ditching and things of that sort. That coincides with the experience of contractors building lines in this area this summer.

In addition to the wage scales that I have obtained from the contractors—and I might say that the scales I obtained from the different contractors did not vary a great deal, they were very close together—we obtained union rates from union headquarters at various points along the line and at cities closest to the various compressor stations, and we have used those rates as wage levels in the calculations which we have made.

905 At the time this line was constructed we made the studies of the construction of major portions of the line, and at that time we obtained from the contractors the wages which they were paying and all of that information. That was for a specific job of constructing a

pipe line. As to what we have done now, however, we have seen a wide range of contractors and did not limit ourselves to the same contractors who constructed the pipe line in 1930 and 1931, although some of the contractors that we have interviewed this summer were the identical contractors which constructed portions of the system when it was originally constructed. There is not a wide range of contractors who do this particular kind of work. There are probably not to exceed 7 in the country equipped to do pipe line work of this kind. In investigating the present level of wages as June 1, 1939, I consulted with five contractors. Four of these five had done some of the work in connection with the construction of this particular pipeline system. There are only two other major contractors who are prepared to do this character of work. I did not consult with these other two because one of them is located in California and the other one in Texas, and I did not have time available to see them.

Among the contractors I consulted in this investigation were: Williams Brothers Construction Company of Tulsa, Oklahoma; Sheehan Brothers Construction Company of Tulsa; Kelly-Dempsey Construction Company of Tulsa; Smith Brothers Construction Company of Kansas City, Missouri; and Truman-Smith Construction Company of Eldorado, Kansas. Of these five the Kelly-Dempsey Company did not handle any work in connection with the original construction of defendants' pipeline.

At the time that this pipeline system was constructed the prevailing common labor rate, for example, was 40 cents an hour over the entire pipeline system. Forty cents per hour was paid in all of the states as the basic common labor rate. There was some common labor in Illinois that was paid 50 cents per hour. At the present time the prevailing wage level for common labor in the states where union labor would not be employed, that is in Texas, Oklahoma, Kansas, and Nebraska, is 50 cents an hour, and in Illinois it will average 80 cents an hour, as contrasted with the scales originally paid. The scales for skilled labor have advanced not quite in proportion with common labor rates, but they have advanced substantially, particularly in the Illinois section.

Our time studies and the data we have collected since 1925 disclose that weather conditions have a great deal to do with both the time that is required to construct the line and the cost of constructing the line. I know of my

own knowledge, and I also know by authority of the weather bureau that weather conditions were exceptionally good during the period when these pipelines were under construction. That portion of the line across the State of Iowa was mostly laid in the winter time, and that winter was the most open winter that had occurred in many years, and much more open that has occurred since in the State of Iowa, both as to temperature and as to rainfall and snowfall. The weather conditions, as reflected in any computations which we have made, have been reflected through the use of these time studies, and, of course, a time study made of construction where adverse weather conditions prevailed, and unusual weather conditions prevailed, would not result in data which we would be warranted in using as a basis of computation in future years. In other words, if, during the time of construction of this particular pipeline, adverse weather conditions had prevailed, the data which we obtained should not be interpreted to apply to average weather conditions. So we wanted to satisfy ourselves that the data which we obtained during the construction of that line was obtained during a period at least of average weather conditions. If this pipeline were about to be reproduced and other weather conditions prevailed than prevailed during the time when it was constructed, the figures we have would, I believe, be too
906 low from the standpoint of the cost of construction.

I do not believe that they might also be too high. I am not a weather expert and I have not attempted to forecast any weather conditions. (Motion by Commission Counsel to strike the witness' testimony that the figures would be too low.) I do not know how many days of interruption that they had during the construction period. I know the temperature and rainfall conditions during the period of construction which are the things which mostly influence the time and cost. It is conceivable that if the line were constructed at some other time since 1931 the time would be longer or shorter, more expensive or less expensive. In compiling our unit cost and basing it as we have upon these time studies, we have naturally assumed the same weather conditions as existed at the time the studies were made and at the time the line was constructed, which were extremely favorable weather conditions. I mean by that I used the same time of construction period, the same number of days, and so forth, as that actually occupied by the construction of the line at the time it was built. I assumed the same identical weather conditions which prevailed in 1930 and 1931, and they were extremely favorable.

In making up these time studies, or rather applying these time studies to the work which we have had in hand in connection with this assignment, I gave effect to such changes in methods of construction and the introduction of such new technological improvements as have come along since 1930 and 1931 and adjusted the labor to meet those changed conditions. We assumed in all cases that the most modern construction methods would be used.

I pass now to another phase of the work which I did personally, namely, the valuation of the lands owned by these companies. The valuation of land is a specialized subject. I was not familith with the value of the lands through the areas traversed by this pipeline system, and for that reason we employed the services of qualified land appraisers in the various areas in which this company owns land in fee. These appraisers were given a description of the land, a plat showing its areas, and were asked to appraise the land as of the date of the valuation and to furnish us certificates of appraisal, and those local realtors or appraisers were paid for their services.

I explained to them at the time I asked for these appraisals that we were not talking about land purchase for agricultural purposes but were concerned only with the small tracts, the size of those owned by these companies, for special purposes such as these lands have been utilized for since being acquired by these companies. I have not personally purchased that type of land. That is, I have not personally executed the purchase, but I have been familiar with purchases of the nature mentioned, and have seen the dates and records of purchases of land of this nature in numerous instances. By way of example I have seen the recorded costs of each purchaser of land owned and purchased by the Natural Gas Pipeline Company of America and the Texoma Company. In some cases I have also seen the recorded cost of the adjacent property used for agricultural purposes, such as ranches or other property. However, I would not say that I have seen such recorded costs in the majority of cases. (Objection for Commission counsel to the witness' qualification.) In general, my ability to testify on this subject arises only in that I have seen that information disclosed from the records of companies which I have examined, and through the connection which I have had with operating companies, and knowledge of the purchases which have been made during that period of time. In a great many cases I have gained the knowledge in connection with studies calling for that information in the valuation of properties other than that of Natural Gas Pipeline Company of America and Texoma Natural Gas Company. I have accumulated this information over a period of about 20 years. For a period of 3½ years I was directly connected with an operating company at Bartlesville, Oklahoma as an employee particularly charged with making valuations and studies for rates, and other general engineering matters. Although I did not make the actual purchases of lands for that company I have knowledge of practically every such purchase in that period of time. Those transactions pertained to land adjacent to a transmission pipe line. (Objection of Commission counsel overruled.) In the majority of cases a pipeline company, a gas transmission company, or an oil pipeline company, is forced to pay a higher price in the acquisition of land than is the prevailing price of the acquisition of land for purely agricultural purposes, and there is a very good reason for that.

In the operation of a natural gas pipeline system or oil pipeline system the flow of the product handled depends upon the establishment of the pressure differentials at various points along the system. Those points are confined to a small area for the various compressor stations, and these stations must be constructed within certain small geographical areas. The site on which they are located must also afford a protection against damages from floods and weather disasters and must be located with the advantage of a permanent water supply. This narrows the available land down to quite a small area, so that it is necessary to make the purchase in this particular area, regardless of what price the company is eventually forced to pay for it. It is my observation that they almost always have to pay well for it.

907 There is another fact which must be considered there, and that is that these companies did not have the right of eminent domain in the State of Nebraska or in the State of Illinois, and it was impossible for them to condemn land for the purpose of stations. I do not believe they had that right in Iowa at the time they constructed the line, but I understood that they have it now although they have not exercised it. The farmer who owns a 160-acre farm or a farm of a greater or less size, or a rancher who

may own a substantial tract of land which he uses in connection with the grazing of stock, may or may not be willing to sell 30 or 40 or 60 or even 80 acres, as in the case of the Fritch station, off his farm or off his ranch for the conduct of an operation such as that of these pipelines on these station sites. (Objection by Commission counsel overruled.) I can think of two or three reasons why a farmer would not be willing to sell 20 or 30 acres off his farm for a station site for a pipeline company at the value of that land for agricultural or ranching purposes. The first is that his whole economic scale of farming is predicated on dividing the farm into pieces, devoting 15 acres to his cow pasture, another 15 acres to the cultivation of wheat, and that fits into his balanced scheme of farming. Now if the pipeline company or anybody else attempts to buy his cow pasture, he is naturally going to charge more per acre for the cow pasture than he would for the farm as a whole because it would split up his whole scheme of operations. It would leave him less land than he has been utilizing in the making of a living. Such a situation is similar to what is commonly known as severance damages.

The second reason is that the construction of any natural gas pipeline system presents a certain hazard to persons living in the immediate vicinity, and if I were a farmer I would not want a natural gas pipeline company compressor station on one corner of my farm.

I made use of the figures I obtained from these various boards and realtors who made the appraisals and who have advised me of their judgment as to what would have to be paid for lands to be used for the purposes of these pipelines. They are the figures that we have used in setting out the reproduction cost of these lands in fee and they are incorporated directly into our report. In total these reproduction costs are below the actual costs of the lands. I think that one or two parcels may have been valued in excess of their cost, but in total they are below the actual cost to the companies. As to ascertaining the present day cost of the rights-of-way for the pipeline and the telephone system, and any other rights-of-way that we found to be owned and used in their operation, we first made a careful inventory of the actual right-of-way contracts owned by the companies. We consulted the cost records of the companies and determined the cost incurred for the purpose of these rights-of-way, together with the cost of acquisition, that being the cost of the man who went out and made the purchases and the cost of abstracting the agreements and recording the instruments, the traveling expenses, legal expenditures, and items of that nature.

The cost of acquiring pipeline right-of-way has steadily increased ever since the first pipeline was constructed. It has no depression at all. Every additional pipeline that is constructed any place in the country makes it more difficult for the next pipeline to secure rights-of-way on anything like a comparable cost, and for that reason we employed the services of an experienced right-of-way man, a man who had actually purchased a great deal of this right-of-way owned by these companies and who had actually been engaged in that type of work since that time. We sent him out over the pipeline system to interview farmers, land
owners, farmer organizations, realtors, banks, and to
908 report to us the cost of acquiring similar contracts for
right-of-way at the present time.

He covered the entire length of the line and all the rights-of-way from Joliet clear to the Texas Panhandle. He reported his findings and determinations to us, and we have used these determinations and incorporated them in our report.

As to the costs of securing or making the actual purchases, we determined the relative wage scale paid to right-of-way agents at the time the line was constructed and at the present time and have increased those costs in that proportion.

A right-of-way is just an easement as I understand it, and the land occupied by the right-of-way reverts to the farmer ordinarily, as soon as it is no longer used for the purpose for which it is granted. The pipeline company does not buy the land itself but merely the right to cross it and lay, maintain, and operate a pipeline in the land.

In addition to the mere easement and the other costs involved in the acquiring of a right-of-way, a very substantial portion of the total cost is represented by payments for the damage to the crops during the construction of the line.

I have seen right-of-way contracts covering the acquisition of rights-of-way extending back as far as 1886, or 1881, and I have seen rights-of-way contracts in that same immediate vicinity acquired in 1936, 1937, and 1938. In one particular area that I have in mind I have seen an executed right-of-way contract providing for 5 cents per rod for the right-of-way, and I know at the present time that company would be exceedingly fortunate if they could purchase a similar right-of-way for $5 a rod. This remarkable change in the cost of obtaining rights-of-way is due principally to visiting between the farmers. When a pipeline system sets out to secure rights-of-way, in order to obtain it in the most economical manner they will send a large force of agents out to make these purchases. The first purchase that the first agent makes from John Jones, in the next half hour has been told to Bill Smith, who owns the adjoining farm, and frequently the price at which the first man sold is exaggerated, and so the news spreads. The fact is, it soon becomes common knowledge that a pipeline is about to be laid in the territory, and the farmer will remember that two years ago he got $2 a rod from some other company, or somebody else got $2.50 from some other company. Thus the price goes up year after year.

For this reason to acquire rights-of-way we send out large forces in order to try to close it up quickly, but they do not always succeed in closing it up with everybody. There is always some fellow who is harder to deal with than another fellow. Here again, in the states of Nebraska and Illinois these companies do not have the right of eminent domain, and it is impossible for them to condemn land for right-of-way purposes. That means eventually they must meet the price demanded by the landowner. There is frequently dissatisfaction among the neighbors when one neighbor receives more than the general run of his neighbors receives.

909 Of course the construction company or the company building the pipeline has the option of taking the line around some other way and keeping off of the land of the man who is hard to deal with, but that usually costs more than it does to pay the landowner his price. When he is paid a higher price, it is more difficult to deal with his neighbors when you come back to them for another right-of-way. That is the way it works out in practice. At the time this line was constructed a general expedition was conducted for the landowners, and they were taken down over sections of the line already completed to show them that the construction of the pipeline across the farm was not going to utterly destroy the whole farm. That was necessary before any arrangement of anything approaching a reasonable price could be made.

The term "overheads" is used to include certain elements of cost, always entering into the construction of any projects, that are of a general nature and are difficult to allocate to specific items of property. The general overheads which we have included in our report consist of engineering and superintendence, organization and law expenditures during construction, taxes during construction, administration during construction, preliminary operations, and interest during construction.

By "preliminary operations" is meant the expense of tuning up the system and placing it in a position to operate, together with the necessary costs of carrying such portions of the investment as must be purchased at the start throughout the construction period, and in this latter category I was thinking particularly of the leaseholds—gas leaseholds—owned by the company that must be obtained in advance of the drilling of wells and must be kept alive throughout the construction period by the payment of rentals to the landowner.

We do not assign to each unit, to each pump, engine, compressor unit, building on the compressor site, or any other unit of inert physical property which has gone into the construction of the pipeline, its proper proportion of the engineering expense, legal expense, interest and taxes, and various other things above mentioned, because it would involve a tremendous amount of detailed work and would accomplish nothing in the long run. The method we have pursued washes out with the same result and results in the same amount.

If you will refer to page 39 of Exhibit 125, the method of calculation of these overhead costs is indicated on this page for the property of Natural Gas Pipeline Company of America. "Engineering and superintendence" we have calculated at 4% of the reproduction cost of the property requiring engineering work in connection with its construction. There are certain items of property owned by this company which require no engineering in their construction or purchase. These are such items as tools and laboratory equipment, furniture and fixtures, automobiles and trucks, so we have eliminated them from consideration in calculating the engineering and superintendence. We have calculated the organization and law expenditures during the construction at .3 of 1% of the applicable accounts; taxes during construction at .4 of 1%; administration during construction at 1.5%; preliminary operations at .6 of 1%; and interest during construction at 6⅔%. This is set out in detail to show just what figures those percentages apply to on page 39. The organization and law expenditures apply to all construction accounts but not to certain other overheads which we have calculated.

910 The item of engineering and superintendence, which is the first item enumerated on page 39, is put in at 4% of the total of all costs except the costs involved in Accounts 1013, 1014, 1015, and 1016. I determined that such costs would amount to 4% of the costs to which that percentage was applied in the following manner: In the first place, engineering and supervision in the construction of a project like this can usually be obtained from engineering organizations which specialize in this sort of work. There charges for complete engineering and supervisory service in a project of this kind would probably cost in excess of 5%. It is usual to make contracts of that kind. That percentage, in the case of a property such as this, I believe, would be somewhat reduced because of the project's magnitude. In other words, that service on a small project might run as high as 10%. On a larger project, when it is related to a percentage, the percentage would be reduced, and I believe if this company should contract for complete engineering and supervisory service for the construction of the system on the basis of 4%, they would make a very good deal.

In addition to that, this project was built originally almost in the same form in which it now exists. The additions since the time of original construction have not been extensive, consisting for the most part of additional compressors in the compressor stations.

The company kept a very careful record of all expenditures for engineering and supervision during the construction period, and we made extensive analyses of these expenditures, resolving them into their different component parts, and we have used that as a basis for our computation. In certain instances, where we felt that those expenditures would be increased or decreased at the present time, we have adjusted them accordingly.

We have thought it necessary to make adjustments where labor was involved primarily. In other words, we made a comparison between labor rates, or wages for technical labor, at the time the line was constructed and at the present time, and for the unskilled labor that has entered into these costs. We also made a comparison of traveling expenses, which are a considerable portion of these costs. We came to the conclusion that traveling expenses at this time are approximately the same as at the time the line was constructed. We then added all these costs, adjusted or otherwise, together and found that they would approximate the figure of 4%, and we rounded it out to an even 4%.

As a matter of fact, I know that there were services performed during the construction of this line which were never charged to these companies or never paid for by these companies. Those services were rendered by organizations participating in the construction of the line that owned a portion of the line, and they simply donated these services to the defendants. We have not attempted to carry these costs incurred by the participants into the cost of reproduction in detail. Insofar as that type of service would be rendered in reproductions of the property as of today they do not appear in the engineering and superintendence overhead except as they may be reflected in the difference between the actual amount recalculated and the rounding out to the four per cent. It is very slight amount.

The 4% figure, applied to the property of both defendants, which required engineering, amounts to $1,958,000. My calculation of the actual engineering necessary for the construction of this project and predicated to a very large extent on their actual costs amounts to $1,900,000, a difference of only about $60,000. This would be 3.98%, or something like that, instead of 4%.

911 In arriving at the next item, organization and law expenditures during construction, which is .3% of subtotal 3, we worked out the cost of organizing these two corporations and licensing them to do business in the states where they are licensed. The organization costs include the expense of incorporating both corporations in the State of Delaware, where they are incorporated. There are certain fees in connection with that incorporation which must be paid. The organization costs include the licensing of the Texoma Company to do business as a foreign corporation in the State of Texas and in the State of Oklahoma, and the licensing of the Natural Gas Pipeline Company to conduct business as a foreign corporation in the states of Oklahoma, Kansas, Nebraska, and Iowa. They include also license tax payable to the State of Iowa for permit and the attorneys' fees for organizing the two corporations, the cost of engraving and signing the stock certificates, and the revenue stamps on the original stock issue, all of which totals approximately $31,000.

The law expenditures include the cost of the companies' regularly constituted legal department during the construction period, together with the cost of obtaining certificates of convenience and necessity in the State of Kansas, the expense incident to securing a pipeline permit in the State of Iowa, the legal expense necessary in securing the permits across navigable streams, and that which would be necessary, I believe, at this time in obtaining a certificate of convenience and necessity from the Federal Power Commission, which total, as we have calculated them, approximately $155,000. This amount added to the $31,000 of organization expense would make a total of $186,000, which we have rounded out to .3 of one percent, resulting in the inclusion in this amount of $154,000, or some $35,000 below our actual calculations.

We made no allowance in this calculation for legal services in connection with examining titles to the property owned by the company or anything of that sort, other than what would be normally done as a routine matter by the regular legal department of the company. I made the assumption that the company would have a legal department during its construction period, just as it did when the construction was actually carried on. I made no assumption as to the expense of examining the titles to the leases, because we haven't included the gas leaseholds in any way in this valuation. There is a considerable cost for examining all titles in connection with right-of-way contracts which are included in the report as a part of the cost of the right-of-way.

The next item appearing on page 39, for which I am primarily responsible, is that of taxes during construction, and I have placed it at .4% of subtotal 3. In arriving at that figure we have made the assumption that if this property were to be reproduced at this time it would require approximately the same construction period as it did when it was actually constructed. I have used the same assumption in all of these overhead charges. During the construction period the taxes which the company would have to pay should be included as a part of the cost of the project, and there are four general classes of taxes which these companies would have to pay. The first is the ad valorem tax, the second the franchise taxes, the third, special taxes such as the pipeline inspection permit in the State of Iowa, and the fourth, Federal capital stock tax.

912 In calculating the amount of ad valorem taxes we made the necessary assumption that assessment rates

and tax rates would be the same as those which prevailed on June 1, 1939, and depending upon the assessment dates in the various states would depend the period over which the companies would be taxed during the construction period. The assessment dates are not all the same in all states. For example, in the State of Illinois the assessment date is April 1, and so during the first year of the construction period, when no property was constructed in Illinois, there would be no tax to pay in the State of Illinois. In the second year of the construction period the tax in Illinois would be assessed only on such property as was installed or completed by April 1.

In connection with the gas wells drilled in the State of Texas, we considered that if this property were to be reproduced, a drilling program would be inaugurated which would drill the present wells owned by the company during the period when the pipeline system and the compressor stations were being constructed, so that at the completion of the pipeline and compressor stations, the wells would be drilled and the company would be ready to start off furnishing gas service. In other words, we reproduced the whole property as of the period of the actual construction of the original pipeline.

We reproduced the whole property from a date beginning the same month of the year as the original line was commenced to a date corresponding to the same month in the following year at which the line was completed. We calculated the ad valorem taxes which would be necessary to pay during this construction period, which approximates a year and a half, at $176,500, and the franchise taxes which it would be forced to pay during this construction period at $17,800. The special tax in Iowa for the pipeline inspection permit we calculated at $3,092, and the Federal capital stock tax we calculated at a minimum amount of $4. The provisions with respect to Federal capital stock have been changed by the last Congress, and at this time it would not be necessary, we believe, to declare a stated value of the capital stock of these companies, which would avoid the payment of excess profits tax, and therefore we believe we could declare only a nominal value during the construction period for the stock of these two corporations.

The total taxes during the construction period we have computed as $199,000, and we have rounded that out to .4 per cent, which, when applied, amounts to $205,376, or within $5,000 of the calculated amount.

The next item is "Administration during construction," listed at 1.5% of subtotal 3. In calculating this item of expense we have been guided primarily by the actual experience of the companies during the period of construction. Administration during construction includes amounts calculated for executive salaries during construction, clerical salaries, office supplies and expense, insurance, rent, telephone and telegraph expense, and items of that nature. We determined from an analysis of the records ~~of the~~ company just what those expenditures were at the time of construction for the two companies and have adjusted those expenses reflecting conditions as of June 1, 1939. We have calculated these expenditures ~~to be~~ approximately $774,000, and applying the percentage of 1.5 it results in the figure which we have included in our report of $770,000 for the two companies.

913 I might say here that in the calculation of all these overheads we have considered the two companies as one and have made the calculation for the combined companies and then divided it between the two companies on the basis of the physical properties of one as compared with the other. The figures which we have given are comparable to the sum of the figures shown on page 39 for the Natural Gas Pipeline Company and similar calculations are shown for the Texoma Company on page 65.

The next item of an overhead nature we have included under the caption "Preliminary Operations," calculated at the rate of .6 per cent. In calculating this amount we again were guided by the actual experience of the company. We determined that from the time the physical property was completed over the various portions of the system until gas was first run through the line there was a total expenditure of $142,000. Now this expenditure was occasioned primarily by what we call tuning up the system, turning the engines over and making sure that they operated satisfactorily, filling in small gullies along the pipeline system, and in general cleaning up and tuning up the whole system and putting it in shape for operations. During that period there was a slight credit for gas sold, which we have deducted, or applied it as a credit against this expense. There is also included in this allowance for preliminary operations the expense of rentals on the gas leases during the construction period. The leases would have to be assembled, and were assembled, prior to the drilling of any wells, and we have predicated that expense on the premise that the company owned and carried the exact amount of acreage which they had on June 1, 1939. We analyzed the lease contracts and determined that the average rental per acre which would have to be paid during the construction period was 55 cents an acre. This would have to be paid over a period of two years. We applied as a credit to that rental the royalty from gas used in drilling the wells, which amounts to approximately $12,000, making a total or net charge for the lease rentals during the construction period of $155,000. This added to the expense of tuning up the system makes a total of $297,000, which we have rounded out to .6 per cent, in the amount of $308,000.

The other item remaining is "Interest During Construction." In determining the amount to be calculated for interest during construction we have again assumed that in the reproduction or reconstruction of this pipeline system the same period of time would be required as was required in the original construction. That is a period of approximately 16 months. So we went to the actual construction expenditures of the companies during the construction period and found that during the first month of construction there was 1.58% of the total expenditure made. During the second month there was 5.71%; the third month, 14.32%; and so on throughout the various months of the construction period. On this basis we believed it was reasonable to assume that in the reconstruction of the system the money would be spent at the same rate, and so we took the total of the reproduction cost of those items requiring interest during construction, which happens to be the subtotal that is indicated on the page at which you are looking as subtotal 4. That subtotal for the two companies amounts to $52,781,710, and applying the ratio in which the money was spent, or the rate of monthly expenditures of funds, to this amount we determined that in the first month of construction there would be a total expenditure
914 of $833,951; in the second month the expenditure
would be $3,013,836; in the third month, $7,558,341; and so on during the construction period. The expenditures during the fourth month were $6,286,302; the fifth month, $3,589,156; the sixth month, $4,797,857; the seventh month, $5,183,164; the eighth month, $3,837,230; the ninth month, $3,610,269; the tenth month, $4,380,882; the eleventh month, $3,684,163; the twelfth month, $2,047,930; the thirteenth month, $1,382,881; the fourteenth month, $717,831; the fif-

teenth month, $791,726; the sixteenth month, $496,148; the seventeenth month, $337,803, and the eighteenth month, $232,240.

In making this calculation we found that gas was actually being delivered after the sixteenth month, and the expenditures in the seventeenth and eighteenth months were largely carry-overs, representing the lag between construction and final payments when entered on the books. So the expense in the first month would draw, or should have interest calculated on it for a period of 16 months; the expenditures the second month for a period of 15 months, and applying an interest rate of 8% per annum results in a percentage of 10.67% of the expenditure during the first month. This percentage of expenditure when multiplied by the portion of the funds expended during the first month results in an amount for interest during construction on that first month of $88,983.

The calculation was then extended for each of the succeeding months and resulted in a total amount of $3,533,059, which is an overall percentage of 6.69%. We rounded that figure out to 6⅔%, which resulted in an amount of $3,520,540, as compared with $3,533,059, as actually calculated. In rounding it out we reduced it from 6.69% to 6.66⅔%.

I used the rate of 8% per annum after discussion of the matter with Mr. Hamilton and after consideration of the rate which these companies had paid as interest for funds during the construction period, coupled with the fact that interest during construction is merely a portion of the return on funds invested during the construction period and on which the investor is deprived of any earning unless it is added to the rate base. I believe that the amount of 8% per annum is a reasonable figure. In other words, through the calculation of interest during construction we have simply made provision for the money which was invested in this enterprise to yield compensation during that period of construction at the rate of 8%. The money was idle during the construction period so far as affording any return to the investors was concerned. The company actually paid 8% for the money that it used in the construction of this pipeline. This interest was paid to the participants furnishing the funds, who later became the security holders of the company.

By "Working Capital" is meant funds which an operating company has tied up in the conduct of its business and which are currently kept on hand. The operating com-

pany would be deprived of any return on these funds unless they are included as a part of the rate base. It is usual, therefore, to include the amounts tied up in working capital as a part of the rate base. We arrived at the proper amount to be set aside as working capital for these companies from the actual experience of the companies as of June 1, 1939. Defendants employ working capital in five different ways. First they have funds currently
915 invested to meet current operating expenses over that portion of time between which the services are first rendered and payment is received for those services. I went through the payments received from the sale of natural gas for a period of two and one-half years and found that there was an elapsed time of an average of 49.22 days between the beginning of service and the time when the check was received in payment for that service in the office of the company. That means that these companies have to provide cash for operating expenses and have that cash currently tied up in the conduct of the business for a period of 49.22 days.

I then determined which operating expenses required cash to be invested currently, excluding those expenses which were not paid until sometime after they were incurred, such as Federal income taxes and items of that nature. I also excluded the item of regulatory expense because that is a non-recurring expense, and while it takes working capital at this time, it will not require any working capital after this case or similar cases are disposed of.

I excluded also from consideration the purchased gas, because the gas which the company purchases is not paid for until after cash is received from the customers to whom the gas is sold. We found that applying the factor of 49.22 days divided by 365 for the entire year, and taking the operating expenses over a period of years, that they had currently invested to meet operating expenses as working capital $348,000.

They also had cash invested in the way of minimum deposits in banks to maintain these banking connections. No bank will handle the volume of checks which these companies issue in the course of a month without requiring a minimum deposit to be left on hand in that bank, and I determined from the cash balance of the company that that minimum approximated $150,000.

The third portion of this working capital is the cash currently invested in prepayments or expenses paid in advance of actual charge. These prepayments are for the most part prepaid premiums on insurance policies, and I found that they had on the average $69,000 currently tied up in such prepayments.

The fourth item is that of materials and supplies which the company currently keeps on hand for making repairs, minor extensions, and things of that character. They might be termed warehouse stocks. I determined that the average amount which they had in warehouse stocks amounted to $379,000.

The last item is the gas which is currently in the lines and which is there at all times and must be either purchased or produced originally. The company is never able to sell it until it finally ceases business, and that item for gas in the lines is carried on the companies' balance sheets at $27,900.

The total of these five items amounts to $974,638, which I have rounded out to $975,000 as the necessary amount to be allowed as working capital. From my experience in valuation work I find that this is a relatively low working as compared with that employed by other pipeline companies.

916 I have a break-down of the part of this expense which has been allocated to Texoma Natural Gas Company on page 65 of the same exhibit. The total figure which I gave of $975,000 applies to both companies, and it has been distributed between the two companies in the ratio of their physical property. These break-downs are found on pages 39 and 65. The combined figures are shown on page 1, which is a summary of the total figures found for both companies.

In general the structural overheads have been depreciated in the same ratio that the physical property has been depreciated. We find it proper to depreciate such charges as engineering services, legal services, administrative services, interest, taxes, and these other items of overhead because they are primarily labor charges, and we believe they should be depreciated the same as the other labor entering into the construction of the pipeline, and for the further reason that if this company is to be amortized, so to speak, over its useful life, provision must be made for the amortization of these amounts. In other words, these charges are merely a part of the cost of the physical property and have to be depreciated along with the other costs of the physical property when you apply the depreciation to that cost and if they are related to certain units of property that should be retired along with the retirement of those units. We have not depreciated the overhead item of organization and law expenditures because this is a corporate expenditure and does not have to do with the physical property and would remain as long as the company was in existence in its corporate form. Since working capital is not an item of fixed capital, it is a current asset, it is not one of the costs of reproducing and is therefore not depreciated.

On page 1 I have set out in this exhibit the reproduction costs of the items which I have discussed and for which I have stated I was responsible in the making up of this exhibit. On this page are shown also the final figures representing the reproduction cost new of the two properties and the present value of the two properties. The lands in fee and rights-of-way are shown in lines 1 and 2 under the caption numbers 1000 and 1002, respectively. Those numbers correspond to the fixed capital account numbers used by the company. Toward the bottom of the list no account numbers appear. That is due to the circumstance that the company has no account number for engineering and items of that kind and distributes those items currently over the items of property to which they apply.

Based on my experience and on the work I have done in assembling the figures which have been set opposite those items lands in fee, rights-of-way, engineering and superintendence, and the other items following it in the list as shown on page 1, it is my judgment that those figures represent the reasonable amounts that would be involved for those items in the reproduction or reconstruction of the property.

Questions by the Examiner.

I did not personally select the appraisers but I arranged for the selection of them in the various districts. In answer to your question as to whether I know if they were qualified, I can only answer by stating that they were employed with the understanding that they were qualified and competent.

The appraisers who furnished me the figures for the lands in fee and rights-of-way were employed directly by the superintendents at the various stations of the com-
917 pany, who were each instructed to employ the most
competent men that could be obtained. Ordinarily we

would ask for appraisals of similar property to be made by the appraisal committee of the local real estate board; but in this territory where these lands are located there are no real estate boards. These men were regular or professional appraisers. I did not talk with the appraisers directly, but I corresponded with them. I took their certificates and worked from the latter. It was a paper job in that sense. I just added up the total of their certificates to arrive at my total figure. I have in my possession all of these certificates received from these appraisers. They are available. If it had been possible for us to obtain the services of one appraiser who we felt was expert enough to value the company lands and rights-of-way from Chicago to the Texas Panhandle, we would have done so. We actually employed in the neighborhood of fifteen.

I have here a certificate of one of them, Robert Ricks, an appraiser of Amarillo. I do not have here the qualifications of each one of these appraisers, but I do have the qualifications of Mr. Ricks. Some of these appraisers probably didn't furnish their qualifications. A part of this territory is pretty far out in the sticks. I do not believe the company has in its files any statements as to the qualifications of these other fourteen. (Objection by Commission Counsel to qualification of witness overruled.)

Direct Examination Resumed by Mr. Morgan.

The mechanical work of applying the amounts deducted for depreciation as reflected in this exhibit was done by our force. The amounts of depreciation deducted were determined and furnished us by Mr. P. McDonald Biddison, who was retained by the defendants to make a study of existing depreciation and report on that subject. He furnished us the amounts in dollars.

The first three pages of this Exhibit 125 are a letter of transmittal explanatory in general of the work we did. These pages are followed by a photo map indicating the system of these two companies. This map is followed by a table of contents. Page 1 of the exhibit is the final summary indicating the property of both companies. It shows the reproduction cost new and the present value after the application of depreciation figures furnished us by Mr. Biddison. The total of the two columns is shown at the toot of each respectively.

Page 2 is a similar summary of the property of the Natural Gas Pipeline Company of America only, and page 3 is a similar summary of the Texoma Natural Gas Company only. In other words, page 1 is a summation of pages 2 and 3.

Beginning with page 4 is what we term the detailed summary of the property of Natural Gas Pipeline Company of America and is arranged by accounts corresponding to the fixed capital accounts maintained by the company on its books. These detailed summary sheets show the reproduction cost new of each major item of property or group of items, the depreciation deducted, which was determined by Mr. Biddison and furnished to us, and the present value, which is merely the depreciation subtracted from the reproduction cost new. This detailed summary extends from page 4 to and inclusive of page 38 for the property of Natural Gas Pipeline Company of America. Page 39 is a further summary showing the manner in which the various overheads have been applied and calculated as far as the Natural Gas Pipeline Company of America is concerned.

918 Beginning on page 40 and extending to and including page 64 is a similar detailed summary covering the property of the Texoma Natural Gas Company, in which the determinations of depreciation made by Mr. Biddison are shown and deducted from the reproduction cost new in arriving at the present value. Page 65 is an additional summary similar in form to that shown on page 39 and covering the property of the Texoma Natural Gas Company, showing the manner in which the various overheads have been calculated and applied.

The detailed portion of the valuation begins on page 66, and all of the ensuing pages of the report indicate the details of property, together with the unit cost and reproduction cost new of the particular item.

On page 1 I call attention to the fact that under the caption "Present Value" the total is $54,410,492. That figure in my opinion and in my judgment represents a reasonable reproduction cost new of the physical elements entering into this pipeline system, viewed as inert elements or component parts and not as parts of the whole, less the applied depreciation worked out and furnished to me by Mr. Biddison. I point out again that these figures do not include the item of gas leases.

Cross-Examination by Mr. Booth.

With respect to the items of general overhead which I have prepared, I intended to state the principal considerations which entered into my judgment in arriving at the amounts I estimated for each of the items of general overhead. So far as I can recall at this time I have not omitted any principal factor which I considered in arriving at those items in my testimony this afternoon.

Cross-Examination by Mr. Slaff.

I will furnish a list of cases in which I have testified in the last ten years on valuation proceedings and rate cases.

Redirect Examination by Mr. Morgan.

Referring to Mr. Booth's questions, I have the working papers and notes that were used by me in assembling the figures for these items of overhead concerning which I have testified. I have the details of all calculations which I made. I am willing for Mr. Booth or his experts, or Mr. Slaff or his experts, to examine these working papers and ascertain just how I arrived at those figures. They will be available at any time they wish to do that.

Questions by the Examiner.

I had one man go along the entire pipeline and have interviews with farmers, farm organizations, and so forth, with regard to the cost of acquisition of rights-of-way as of June 1, 1939. I cannot tell you the exact number of days that agent was out, but he was out a considerable time. The number of days he was engaged in this work can be ascertained very easily in Chicago. He was out a considerable time in 1938 and again in 1939. I will have that data available at the time of cross examination.

919 In estimating the cost of acquisition wherein we considered wage scales and so forth, we used the same system of acquisition of rights-of-way as was actually used by the company. I contemplated the same method of acquiring rights-of-way. I attempted to use the same number of man hours, assuming that the difficulties that would

be encountered would be the same as those which were encountered.

This item of crop damages is a lump sum determined once and for all, with the exception that in subsequent years when repairs are necessary and the crops are destroyed, the farmer is reimbursed for all damage of that kind. That is charged as current operating expenses. It happens quite frequently that crops are damaged because of repairs made after the line is in operation. I did not use any figure in this cost of acquisition of rights-of-way to represent increase in the difficulty of acquiring rights-of-way today.

(September 1, 1939)

Redirect Examination Resumed by Mr. Morgan.

In my examination yesterday I was asked concerning the number of contractors with whom I checked labor costs up and down this pipeline and the number who were engaged in the building of the pipeline. I gave the names of five contracting firms whom I had consulted on this point and stated that there were four of these contractors who had a part in this pipeline construction. I was mistaken. I should have said there were three. The other one which I thought at the time I testified did take part in this construction work, but which it turned out did not participate, was Truman Smith Construction Company. They are a large pipeline construction organization and have been doing work in that immediate vicinity at this time. They have been so engaged for several years. I believe they made a bid on a part of the construction of this line, but I am not certain on that point.

Questions by the Examiner.

I am certain the appraisers who appraised this property actually viewed it. I didn't accompany the appraisers, and I have only correspondence from them, but that correspondence would lead me to believe that in every case they did view the property.

Redirect Examination Resumed by Mr. Morgan.

As I stated during my testimony yesterday, I was for a period of approximately three and one-half years directly connected with an operating natural gas organization. That organization now comprises the Cities Service Gas Company of Bartlesville, Oklahoma, and my work with that organization was of such a nature that I was familiar with almost all of the activities of that organization. I was familiar with several tracts of land which were purchased by that company during that period of time, knew their costs and the location of the land and the purpose for which it was used. Since that time I have also been quite familiar with the operations of that same company and have made two complete detailed appraisals of all their property, including their lands in fee.

Questions by the Examiner.

I have noted in my experience in that connection that we
were not able to purchase land for our pipeline pur-
920 poses at the prevailing agricultural prices. This is
true in a great majority of cases. It is true with respect to the Cities Service Gas Company at Bartlesville. That is a transmission company and not a distributing company. It is one of the pipelines which transmits gas out of the Texas Panhandle.

My statement concerning the difficulty of obtaining land from farmers or ranchers experienced by the defendants at the time they were getting the land for the construction of their pipeline, including station sites, was based on correspondence which I have seen in the files of the company. I saw this correspondence during the last year or year and a half. It consists of letters in the files that were written as of the time the pipeline was being constructed and dealing directly with the then going on negotiations for the acquisitions of the land. I have also had this information confirmed in my conferences with offices of the company who know or should have known of the difficulties, because they were associated with the company at the time.

921 J. L. WILLARD, a witness for the defendants testified:

(September 1, 1939)

Direct Examination by Mr. Morgan.

My name is J. L. Willard. I reside at Summit, New Jersey, a suburb of New York City. My place of business is at 60 Wall Tower, New York. I am at present and have been for the past 14 years associated with F. C. Hamilton.

I went through the public schools in the city of Denver, and later attended the University of Colorado, finishing there with a Bachelor of Science degree in civil engineering in 1922. During odd times while in the university, I was employed by the Phelps-Dodge Corporation in their coal camps in Dawson, New Mexico. In that work I was with the mining engineering department, and was engaged in survey work of an underground and surface type, and also in making estimates of coal recovered and expected recoveries.

Following my graduation I was employed by the Empire Gas & Fuel Company at Bartlesville, Oklahoma, and was connected with the civil engineering department. I was employed by this company from the summer of 1922 to the fall of 1925, during which period I covered the entire territory of all their gas pipe lines, oil pipelines, oil production and refining properties. By all their territory I mean the territory in the Mid-Continent field.

At the beginning of my employ I was placed in charge of survey parties for the location of pipelines, both oil and gas, tank farms, oil pumping stations, gravity oil gathering systems, location of oil and gas wells, and was also connected with the follow-up construction of gas and oil pipe lines. During the construction of these pipe lines I did considerable checking of materials that went into the project, and after the completion of the project, quite often I had charge of a party making a complete field inventory and check of all of the materials that went into the project. Later in this employment I was engaged in making estimates of the cost of the pipelines, including lines from the Oklahoma district to Denver, Colorado, and also to St. Louis, Missouri. I was engaged in making cost estimates of various accessory equipment to gas compressor stations.

These estimates of cost of constructing these pipelines included all of the costs involved in the construction of the pipeline and the necessary appurtenances used in connection with its operation. That, in a general way, is practically the same as the work of making the valuation of a pipeline after the project is completed. It is necessary to obtain quotations on all materials that go into the project, and estimate labor performances from knowledge of previous pipeline construction.

In the fall of 1925 I was employed with the Cities Service Company, and associated with F. C. Hamilton in the valuation and rate department. I have been engaged in that work from then until the present time.

922 After a preliminary experience of two or three years, I was on the road almost constantly from 1925 until 1936 in charge of appraisals on gas properties located at Denver, Colorado, two valuation jobs in Bartlesville, Oklahoma on the Cities Service Gas Company, a job on the Kansas City Gas Company located at Kansas City, Missouri, the gas properties of the City Light and Traction Company at Sedalia, Missouri, the East Tennessee Light & Power Company at Bristol, Tennessee, the Danbury Gas & Electric Company at Danbury, Connecticut, and was called in, in a consulting capacity, on work on the Republic Light, Heat & Power Company in Buffalo, New York, and the Arkansas-Louisiana Gas Company at Shreveport, Louisiana.

In addition to these valuations on gas properties, I have been engaged in valuations on electric, street railway, water, ice and cold storage projects. The major of these properties include those located at Cleveland, Ohio, the property of Ohio Public Service Company, which covers a large portion of the central and eastern part of the state of Ohio, the Toledo Edison Company located at Toledo, Ohio, the entire electric property of the Public Service Company of Colorado at Denver, Colorado, properties of the Empire District Electric Company, the Lawrence County Water, Light and Cold Storage Company, the Toledo & Indiana Railway, the Lake Shore Power Company, and numerous other properties.

I have made estimates the appraised value of which ran in the neighborhood of from $800,000,000 to $900,000,000. The portion of that of which I have had direct charge—sometimes individually and sometimes in association with other men of our department like Mr. Eastman and Mr. Stoddart, and always under the direction of Mr. Hamilton

—I would say of that total I have been in direct charge of approximately $600,000,000.

I have made appearances before utility commissions, courts, and other tribunals in connection with these valuations matters with which I have worked. I participated in hearings of the Cities Service Gas Company before the Public Service Commission of Kansas in 1931 and 1932, not as a direct witness but as an accessory to the witness. I also appeared in the same capacity at a later hearing on that same property in 1934. I was connected with two hearings before the Public Service Commission of Missouri on the properties of the Empire District Electric Company and the St. Joe Railway, Light, Heat & Power Company. I was present at a hearing before the Interstate Commerce Commission recently held on the properties of the Empire Pipeline Company, an oil transmission company of the Cities Service Oil Company. I testified before a district court in the city of Fort Collins in a condemnation suit brought by that city against the Public Service Company of Colorado.

In 1936 I was sent into the New York office to take charge of the valuation crews who had jobs going on in various sections of the country at odd times. I have visited and consulted on these jobs in many locations. My work has involved the making of reports for attorneys in their work to obtain new securities before the Securities and Exchange Commission, and also before the Ohio Public Service Commission. That was valuation work. I have also been engaged in the establishment of rates for both gas and electric service in various sections of the country.

923 I have had to do with the valuation studies compiled under the direction of Mr. Hamilton on the properties of defendants. In conjunction with Mr. Eastman and Mr. Stoddart, under the supervision of Mr. Hamilton, I was engaged for a period of five and a half months in 1938 in obtaining a complete physical inventory, together with a pricing of that inventory on the properties of the two defendants, and again in 1939 for a period of three to three and a half months I was engaged in that same work in bringing the previous 1938 data down to date.

I was in Chicago, with the exception of a few days, during the entire period of both of these valuations in 1938 and 1939, and had under my supervision a group of men varying from ten to twenty.

It was my duty to organize the personnel that was brought into Chicago to compile this data. In conference with Mr. Eastman I decided that certain men would take charge of certain phases of the work, some going into the field to make a complete physical inventory of all the visible property in the field. After all of the records in the office and the data taken from maps of the pipeline, maps of all compressor stations, meter and regulator stations, had been thoroughly examined, these men were sent into the field to make additional inventory of all of the property in the field and check that inventory with the data that was obtained in the office, and to make any adjustments that were found necessary due to any small changes that might have been made in construction work around buildings or on other small maintenance jobs that had not been properly reflected on the maps from which we obtained the data in the Chicago office.

We made a complete inventory of all of the accessible or visible physical property of these two pipelines. During the field check we had men inventorying, after visiting all of the gas wells in the Panhandle Field, all of the physical property in connection with the top fittings of the wells, fences, signs, meter and regulator runs, together with the meters and regulators, the buildings housing the equipment, and from there traveled to the Fritch compressor station and tabulated all of the equipment in connection with the compressor station, the gasoline plant and the dehydration plant, all of the cottages, warehouses and other items of a physical nature at that location. Our men visited all of the intake meter runs on the various gathering lines. They visited the river crossings where the gates on the headers could be observed, and then traveled from Fritch northward, covering all of the stations in the states of Oklahoma, Kansas, Nebraska, Iowa, and Illinois. I don't want to convey the impression that one party covered all this territory. We had several parties in the field, some working south on the line from the north end and others working north from the south end.

These parties were composed of members of our organization who were employees of long standing. All of those men have been familiar with gas transmission and gathering properties over a period from a minimum of six to approximately fifteen or twenty years.

Naturally we did not dig up and have an inventory made of the number of joints of pipe and the valves and other fittings that are buried with the pipelines. However, 924 men associated with Mr. Hamilton have taken time studies on that line, a very substantial portion of the line, and these men actually saw the pipe going into the ground. We have pictures of it in our office as a part of these time studies, so that we are definitely informed that the pipe is there. In addition to that we had men making time studies of compressor stations where they observed the actual trenching of all of the underground pipe in connection with the stations, and saw the pipe as it was laid in these trenches.

We made a thorough check of the maps of the company and these maps, I must say, are very well kept up and very well made in the beginning. I feel that as a result of these checks of all these maps and of the field checks we made to verify the fact that all items of property shown on the maps actually existed, that the compilation of our inventory is a true and accurate record of all of the physical properties of these two companies with the exception of course of the gas leases. We left the gas leases out because we were advised that the gas leases would be handled by someone else, and were requested to pay no attention to their value. Our instructions were to confine our valuations to the properties other than gas leases owned by these two companies.

In my opinion this Exhibit 125, composed of two volumes, which was identified here and from which Mr. Eastman testified concerning some of the details, is a true and accurate inventory and listing of the property of these two companies as we were able to obtain. In my judgment it encompasses all of their properties except the leases.

This inventory naturally comprised volumes and volumes of data, and it was our task to summarize and tabulate that data in a form, necessary for pricing purposes, to fit the classification of accounts now in use by the companies. It was also necessary to tabulate the data in a form so that we would know what equipment came from the various manufacturers and the quantities of that equipment. The entire inventory was separated, in the case of the pipeline, by States, each State comprising a summation of all of the physical items in connection with the pipeline in that State.

The pipeline inventory was divided into States mainly for the purpose of pricing to reflect an accurate price for pipe in the several States. There are many factors that change the value or the reproduction cost of the pipe, and of the materials, such as difference in freight rates, taxes that are applicable to material in certain States, difference in hauling rates, in labor rates, in insurance rates, such as workmen's compensation, public liability and other insurance that is applicable to labor. By so dividing the pipeline inventory we were able to reflect in each State the proper price for each foot of pipe and for all of the individual accessories of the pipeline.

In the case of compressor stations, that inventory naturally was taken for each station. However, if we deemed it a saving you might say that we could have grouped all of these compressor stations into one lot for pricing. But after investigation it was discovered that there would be no saving in this type of summary in the work that we had to do, as we would have had to average the prices 925 in the various locations and apply that average to all of the material which would result in a distorted price for any one particular item at any one station. So we priced all of the items at each of the ten compressor stations individually. This involved the work of compiling unit costs at ten different compressor stations for a large number of items in the stations that had the same manufacturer's quotations. In the case of pipelines, we priced separately for each of the six States, the pipe that was part of the system in each State.

While this tabulation was in progress, other men were engaged in the work of investigating all the original commitments of the constructing company, collecting over-all purchase vouchers or a large number of the purchase vouchers from the original completion date of the project up to the present time, in order to inform ourselves as to the kind of material or the description of the material that was in the property, and in order to familiarize ourselves with the manufacturer who actually furnished the equipment. After that investigation had been made, we tabulated this property by manufacturers who furnished the equipment or material, and prepared quotation letters for prices as of the valuation date on all of the equipment and materials involved in the system.

We sent these letters to the manufacturers in the various sections of the country. I would judge that we forwarded quotation letters to the extent of 250 to 300, and some of these letters varied from single pages up to quotations involving as many as ten or twenty pages, all containing different items of equipment that an individual manufacturer furnished. In these letters we asked the manufacturers or dealers to quote prices on the material that had gone into this pipeline. In asking for their quotations we asked them to furnish the net price that was available to this company under the consideration of the purchase of the quantity of items that were involved in the entire system, and reflecting all cash discounts and chain discounts that the company would obtain in the purchase of the large quantities that would be necessary in this construction. We received replies to these letters requesting quotations. All but one or two to whom requests for quotations were sent out answered, and those one or two in all probability were answered by other concerns who had since taken over the manufacturing concern that had gone out of business. We received back substantially every quotation that was requested.

I do not mean that we ourselves stated the price which was quoted. I mean that we received back our form on which we had listed the property with as complete a description as possible, and on which we asked them to quote us prices on the basis that I have already mentioned, first as of January 1, 1938 and then as of June 1, 1939. I mean by this that we requested these quotations at two different times in the course of our work for these companies. That was the only way possible to get current quotations on the various items of material and equipment. As we were required to bring our previous work down to date it was necessary, of course, to get quotations as of June 1, 1939 for the work as presented in Exhibit 125. In addition to the prices we got also the weights of all the equipment and materials. We needed the weights in order to calculate freight, hauling costs, and other similar things that involved the weight of the particular items.

926 Next we had to make up forms for the building up of unit costs for each and every item that appears in Exhibit 125. I would judge that there are in the neighborhood of from 12 to 20 thousand unit costs that we made up in the compilation of those volumes. Take the general item of pipeline material as an example. Our unit on pipe has always been the foot. Pipe prices are substantially always quoted by the foot or by the hundred feet, and it is a recognized unit in the industry. It also gives a clearer picture in the report as to the actual quantities that are involved in the system, the magnitude of the system. We added to

the cost of the pipe, the necessary freight, taxes that were applicable, hauling, and labor of installation.

In connection with our quotation letters we obtained the shipping point of all of the material, and an indication as to whether or not the quoted price was an f. o. b. point of shipment or f. o. b. destination price. We knew the destination of all of the material and we formulated a tabulation to obtain freight rates. These freight rates were obtained from established traffic bureaus. I believe our tabulation of freight rates involved in the neighborhood of 1500 tariffs for both carload and less than carload rates.

In the State of Oklahoma, as an example, it was necessary for us to obtain tariffs, both carload and less than carload, for all items of equipment in the Perryton compressor station. The physical property that comprised that station was purchased from locations as far east as the eastern seaboard and as far west as the western seaboard. We obtained the tariffs from the various sections of the country to the destination at, I say, Perryton, Texas, because the town of Perrton, Texas, is the closest town to that station, although it is located in the State of Oklahoma. It was also necessary for us to obtain tariffs on pipe for every destination where pipe was actually shipped to the company during the original construction of the line. In the State of Oklahoma this did not involve many locations, because the pipeline travels through what is known as the Oklahoma Panhandle and does not cover a substantial part of the State. But in that State, as well as every other state, we obtained tariffs, both carload and less than carload, on every point of shipment that was actually used during the original construction of the line. We went through the same detailed computations in arriving at the freight costs involved in the material which would have to be shipped to Texas, to Kansas, to Nebraska, to Iowa, and to Illinois. We have given effect to the differences in these freight costs in arriving at our unit costs. We have applied, with the same degree of detail, these costs to each of the 15 or 20 thousand units which are set out in this inventory.

In figuring these unit costs we used the labor rates that Mr. Eastman had secured, and applied them to our man-hour performance for each and every unit of installation that was compiled. When we received these quotations we very carefully scrutinized all of them, compared them with the data that we had available from purchase vouchers, reviewed them in the light of our own personal knowledge of

equipment extending through a period of some fifteen or twenty years and put them through every test that we knew to assure ourselves of their accuracy. In some cases it was necessary for us to further correspond with manufacturers in an attempt to justify in our own minds that the full information we had requested had been reflected in the
927 quotations. As a result of a few of these additional
letters that had to be written, we obtained lower quotations on certain items of equipment. We justified in our minds before the use of any prices, the fact that that price was the correct price as of the particular date for which it was quoted. We gave careful consideration to all of these prices almost to an equal extent. As to the pipe prices, due to the fact that there was a tremendous quantity and a very large value involved, we were particularly careful in observing the quotations that were given us in the case of pipe. We recognized that due to the tremendous quantities involved in this system, and due to the condition of the market at the particular time, the prices of pipe called for a special investigation, and Mr. Hamilton conducted this investigation and will testify as to his findings. We used the figures given us by Mr. Hamilton as the cost that this company would have to pay if this project were to be constructed at this time. We received quotations from pipe and all other manufacturers, quoting prices as of January 1, 1938 and as of June 1, 1939. These letters, of course, were sent out at entirely different times. We knew the conditions of the market all the way through and we knew the quantities involved when we sent out these requests for quotations, and we made a study of prices available both before and after the quotations were received. We went through all purchase vouchers of the company for the years 1938 and 1939 and made the study in that form. Then, after the quotations were received, we thoroughly went over them, but decided that Mr. Hamilton should make a special investigation of pipe prices. Mr. Hamilton will explain just what he did and whether or not the prices he gave me were higher or lower than those set out in the quotations. I may say, however, that the prices we used were below the quotations in general. There may have been some exceptions. By that I mean that in general the ultimate net result was to use a lower gross pipe figure over the whole pipe consideration.

The taxes entering into the cost of this material are not the same character and type of taxes that Mr. Eastman was discussing when he was going over the overheads and mentioned and discussed the items of taxes during construction. These are entirely different taxes, known as sales and use taxes on material and equipment. These taxes are paid at the time of the purchase or at the time of the use, as the case may be, of the material. There is no duplication whatever of the taxes which we have figured into these unit cost computations and those taxes that were under discussion by Mr. Eastman in his treatment of the subject of overhead costs.

The term "stringing cost" as applied to the construction of a pipeline is that cost involved in the unloading of the line from the cars of the railroad siding, hauling it out to the right-of-way, and stringing or distributing it along the right-of-way. Our costs for that item were determined from the actual man-hours used during the original construction of the line, taken from our pipeline time studies, with labor rates as of the present time applying to the man-hours, and the prices of equipment used in the hauling of the material. In the case of compressor stations we corresponded with hauling contractors who were actually engaged in the hauling of this material from the railroad siding to the compressor stations during the original construction, and were familiar with the quantities involved, the type of material involved, and the various terrain at the several locations where the material had to be hauled. We used quotations from these hauling contractors in the case of compressor station material and equipment.

928 This is not the type of hauling that we could go out and employ the local truck owners to perform. In the case of pipe we have joints that are 40 feet long and call for special equipment, and in the case of compressor stations equipment you have iron frames of these gas compressors that are so heavy that it calls for very special equipment in the hauling and handling of that material. The hauling of this type of heavy equipment and material is a specialized line of work, but there are hauling contractors equipped to do that work in the particular districts.

Taking into account all of these items after we had grouped or separated the different types of equipment by states, and by stations as I have testified, we applied the cost of the material at the factory, the freight, the hauling, the construction, the insurance, the sales and use taxes, and incidental costs going with labor such as compensation insurance and that type of cost as we found those charges and costs to exist in the several states or at the several stations. Charges like insurance, workman's compensation and public liability insurance, like the other elements of cost, vary substantially in the several states. We added all of those items to which I have just referred into a unit cost which appears in Exhibit 125 as the unit cost of the particular item. In some cases there are many unit costs that were added together for pricing in Exhibit 125 for the reason that we found it necessary to condense a large number of small items that go to make up one particular unit. If we had gone into all the detail we would have doubled the size of that exhibit. However, I have all of the details of all of the items, and these details are available and we will make them available for the counsel and the engineers of the two commissions who are involved in this hearing.

In conjunction with Mr. Eastman and Mr. Stoddart, I had supervision of the compilation of this entire Exhibit 125. In general I had to do with all phases of all of the items listed on page 1. Our work is of such a nature that we must collaborate with one another at all times. The entire two volumes have been compiled in a form suggested by Mr. Hamilton and obtained through consultation or collaboration with my associates in this work, and the various details, of course, were passed on to men under my supervision. I took personal responsibility for presenting all of the general subdivisions listed on page 1 of this exhibit except those items listed as lands in fee, rights of way, gas wells, and those items of overhead beginning with engineering and superintendents, and so on, down to and including working capital. Mr. Eastman took responsibility especially for the figures in line 1, Account No. 1000, "Lands in Fee", Account No. 1002, "Rights of Way", and those overhead items and working capital down at the end of the list. Mr. Stoddart is especially responsible for the item listed under the caption "Gas Wells" and he will testify concerning that item. He was directed especially to devote attention to the matter of reproducing gas wells, or computing the cost of reproducing those wells. He also collaborated with us on other items.

By way of general explanation I would like to say that this exhibit consists of three parts. The first three pages are the grand summary of the individual companies and the sum of the two companies; Pages 4 to 64 are what we called a detailed summary and consist of a recapitulation or a condensation of the detail which appears beginning on page 66 and continuing on through to the final page of the second volume. 929 There are several reasons for this condensation or recapitulation. First, it enables an individual to run through each and every item and find the total reproduction cost of the various items in each account in each State in total, and will afford a general over-all picture of the entire property. In addition to that the summary is made up in this form for the convenience of an application of depreciation. I mean the depreciation worked out by Mr. Biddison concerning which Mr. Eastman and Mr. Hamilton testified. Under this column of "Depreciation Deducted" the figures were obtained from Mr. Biddison, and the only work that was involved, as far as my direction was concerned, was just the mathematical subtraction of his figure to obtain our present value column on these detailed summary sheets. The figures for which I have assumed responsibility, are those under the caption "Reproduction Cost New."

For convenience in following this report there has been an index placed just preceding sheet one, and the details of ~~Account~~ 1005, which is main lines, and which contain the figures on page 8, are shown on pages 109 to 132. On page 109 we find the beginning of the details of the main line in the State of Oklahoma, and continuing on to page 110 and 111, being totaled on page 111, to $1,292,094, which is the figure that appears on page 8. On page 109 we began with the listing of the detailed items included in the main line account in the State of Oklahoma. First we list the steel pipe and a description of that pipe as electric weld, plain end, 40-foot joints, 24-inch pipe with a weight of 86.908 pounds per foot. The detail indicates that in the State of Oklahoma there were 194,578 feet of pipe priced at a unit cost of 3.6463 dollars per foot. This same indication of the detail proceeds on through the right of way grading, the trenching both earth and rock, and back filling of all of the earth and rock; the welding of the line, the dresser couplings that are part of the line, the footage of enamel paint, the painting of the couplings, and on page 110 we list the two river crossings that are located in the State of Oklahoma, namely, the Beaver and Willow Creek river crossings. These two items show no amount for a unit cost because in the buildup of the price of a river crossing there are so many individual items involved, every river crossing being different from any other river crossing, the complete detail of all of the items of physical property in connection with each river crossing would take up several pages.

All of the unit costs going into the total of $215,843, shown as the first total figure on page 110, are included in our working papers with a unit cost for each and every item that is a part of the river crossing. However, in this description we do give a general over-all description of what the crossing consists of, the size of the lines, the kind and length of the joints, the weight of the pipe per foot, and the actual footage of each different sized line in the crossing.

We then go on to highway and railroad crossings which to some extent are similar to river crossings, the detail of the unit costs consisting of many unit costs which are added together in our working papers. The main line gate valves that are a part of the line in the State of Oklahoma, the blow-off valves, valve boxes, the drips and drains that are located along the line, the fittings such as "T's" and nipples in bridges that are necessary in river crossings for the purpose of line walkers, and the other accessories such as sleeve houses and pipe racks, all have their individual
cost listed and their quantities listed, and by the multi-
930 plication of the two we would get total figures which,
added together, give us the total for the main line
account in the State of Oklahoma of $1,292,094.

Questions by the Examiner.

Along the line of a pipeline they invariably have sleeves for the maintenance of a line. The sleeve house is a small house that houses a sleeve that may at some time during the operation of the line be necessary to place over the pipe to take care of any particular emergency that might come up. You might say, in a sense, it is a small storage house for the sleeves that are located on the line. They locate the sleeves on the line just as the railroads do spare rails.

On page 109, where we have the trenching and back filling, 24-inch, the figure stated is the average for the entire State of Oklahoma. It very truly reflects the cost in the State of Oklahoma. It is based on the actual present construction.

The highway crossings of 28-inch are not culverts. At all or practically all highway crossings the specifications of the state, county, or other subdivision that might have charge of the highways require the pipeline companies to install casing over their regular pipe with vents coming out of the casing. That is why the pipe is a 28-inch. It circumscribes the 24-inch pipe, and at each end is welded through a coupling to the 24-inch line, and vent pipes come off of that casing from each side of the highway or railroad crossing. It is just to take care of anything that might happen to the pipe under the highway or railroad. If leaks should spring in the pipe underneath the highway the gas, instead of coming up through the ground into the highway where it might be set on fire by an automobile, is vented off to the side.

Direct Examination by Mr. Morgan Resumed.

This first line, 194,578 feet, is the quantity of footage of 24-inch pipe line that is found in the State of Oklahoma. We used the description electric weld plain end 40-foot joints of 24-inch pipeline, weight 86 and a fraction pounds per foot in the State of Oklahoma instead of describing the seamless pipe because that is the kind of pipe that is in the State of Oklahoma. In each state we have used the same kind of pipe that was actually used in the construction of this pipeline at each location where we have reproduced the cost.

The figure, 3.6463 dollars, represents the per foot cost of that pipeline. That amount reflects the cost per foot of that particular kind and size pipe, and includes not only the cost of the pipe at the mill but also the freight to the state, the use tax levied by the State of Oklahoma, which is applicable to all interstate purchases, and it includes the hauling, stringing, laying and lowering of the line into the trench. Having built up all these items into one total, we multiplied the number of feet by the total cost per foot and arrived at this first total of $709,490. I am referring to the first unit cost on page 109. The unit cost is 3.6463 dollars per foot for the kind of pipe that was used in that state. That price is obtained from an f. o. b. mill quotation of 2.6551 dollars per foot for the pipe.

To that I have added freight in the amount of .6605 931 dollars per foot. That freight has been obtained by actually calculating the deliveries of the pipe in the entire State of Oklahoma to the many destinations of the State of Oklahoma and dividing the total number of dollars of freight so obtained by the total footage of pipe in the state. It may not reflect any particular freight rate to any particular point in the State of Oklahoma. To that has been added the cost of a shop priming coat on the pipe. All this pipe, when purchased, was given a coat of shop primer to protect it against rust enroute to its destination. This amount has been quoted to us by the manufacturer at .0225 dollars per foot. I then added a state use tax which is applicable in the State of Oklahoma not only to the material cost but to the freight necessary to get the material to its destination. This tax amounts to 2 per cent of the foregoing items, or .0668 dollars per foot. I then added the cost of unloading and stringing the pipe at .0938 dollars per foot, and the cost of laying and lowering the pipe at .1476 dollars per foot. All of these items total up to 3.6463 dollars per foot which is found as a unit cost on page 109.

The items included for unloading and stringing and those included for laying and lowering are obtained by application of the present-day labor rates existing in the State of Oklahoma to the time study man-hours which were developed from time studies taken on this pipeline, and include an allowance for all contractors' equipment that was used in connection with the stringing and laying and lowering of the pipe.

We developed the unit prices of a cubic yard of grading, or earth and rock moved in trenching, and the other different units that appear on this page, and the succeeding two pages, by the same detailed steps, insofar as those steps were applicable to those units, that we took in the case of a foot of pipe. Some of these unit costs, for instance the grading cost listed here, include no material other than the using of contractors' equipment. That is a labor performance with the machines and other equipment necessary to grade the tops of hills and the rights of way in general for the purpose of enabling the ditching machine to travel more uniformly along the right of way and to eliminate as far as possible the bends in the pipe.

Speaking of bends I would like to indicate that in this cost of laying and lowering there is an amount included for the necessary over-end and sag bends that must be made in the pipeline when it is going over a rolling country or through draws or ditches. We allowed for the same bends of one type or another that we find from the records were made in the pipe that was actually laid there by defendants. We applied the use of our time study all the way through, and the man-hours for making bends were reflected in the time study together with the equipment that was used. We knew where to provide for a bend because the bends run along the system with the draws, the rolling country, and we have applied in the case of Oklahoma the man-hour study which applies to that particular section of the country. That study shows the work of that particular character. We did not count the bends in our inventory as they are properly reflected as a part of our time study man-hour performance. The performance of this bending is one of the things that was done by the men whose man-hours were computed in our time studies.

932 I have the detailed breakdown of each of these other items appearing as the unit cost in the third column shown on pages 109, 110, and 111 among our working papers which are and will be available to counsel and the engineers of the two commissions. These include also the details behind those two total costs on river crossings which are not indicated as a unit cost on page 110. All these working papers will be available to the engineers and counsel of the commissions at any time they desire. However, if it is not at the immediate time, I would like to have some notice as they comprise two or three immense boxes that would have to be put together and shipped. We have many jobs going on in various sections of the country and we would like to avail ourselves, at those jobs, of all of the information that we have that might assist in furthering any present or future work. These details can be shipped here (Washington) or made available at any location at any time we are notified.

We will go next to one of these compressor stations. As indicated by the index, the detailed summary covers pages 4 to 65, and that part covering the Texoma Natural Gas Company of which the Fritch compressor station is a part is on pages 40 to 64. The Fritch compressor station in the detailed summary begins on page 55, and the summary of the details continues over to page 56, listing all of the items in the Fritch compressor station and totaling the entire reproduction cost new to $2,258,071. All the classifications are not listed individually. For instance, you will find "Machine shop equipment" on page 56. Now that caption includes all of the machine shop equipment consisting of lathes, drill presses, hack saws, and such other items of machine shop equipment. The list includes everything located at the Fritch Compressor Station which is properly chargeable to Account 1006 "Compressor Stations". There are other items at the Fritch station which are located in other accounts. The detail of the compressor station account for Texoma Natural Gas Company is on pages 758 to 795, which would be in Volume 2. On page 758 in Volume 2 we find the listed details of the auxiliary building in the Fritch compressor station, which is carried over to page 759. All the units on which we computed their cost on a unit basis are set forth in those pages beginning on page 758 and ending on page 795. I would like to add at this point the fact that in the listing of this detail in the valuation we have carried it all by the classification of accounts used by the company, recognizing that various classifications are in use by different companies. Due to the possibility of a new classification being necessary, we have attempted to list all of this detail in a form that could be readily converted to almost any classification of accounts. You will notice in the Fritch compressor station we have indicated each and every item of a structural nature, like buildings, in alphabetical arrangement first and then followed with items of equipment in an alphabetical arrangement.

We have worked out the number of units, whether stated in terms of weight, or dimension, or length, or quantity, whatever the manner of stating may be, and the unit costs of each of these units in this compressor station in the same detail and by the same method that we have worked out the details concerning the unit cost of pipe in Oklahoma. We used the different crews necessary for installation of the different items and applying taxes where they are applicable, and such labor rates as are applicable in the State of Texas. We do not use the same factors, of course, but we use the same method of applying such
933 factors as are applicable to each unit cost and break the unit costs down into the same character of detail which we mentioned when we were talking about the per foot cost of pipe, or the other unit costs in the State of Oklahoma in connection with the pipeline.

We went through the same procedure in each of the other compressor stations, at all of the meter and regular stations, at all warehouses and other locations along the line that had equipment belonging to the company, that was apart from the compressor station. Items like meter stations and regulator stations, meter lines and regulator lines, are distributed through the exhibit at the locations or in the states where they actually occur in the system. These main line meter stations are the meter stations on the main line only and have nothing whatsoever to do with branch or lateral lines. In the State of Illinois we have a main line meter and regulator station that is a sales meter as it is the termination of the line where the final sale is made. In the State of Iowa we have other meter and regulator stations that are a part of lateral or branch lines from the main line. These appear on another account. These items do not occur on the main line which is the reason they are not listed in this account.

Going now, for the purpose of illustration, to the State of Illinois main line, I call attention to an item of $5,633,212. The detail of this amount, which is indicated on page 8 for main line in the State of Illinois, commences at page 125 and extends through to page 130, where the total of all of the detail on pages 125 to 130, inclusive, is tabulated. The pipe with which we deal at this point is exactly the same kind of pipe with which we were dealing in the State of Oklahoma except that this pipe has a bell on the end of it. This is just a sort of flare on the end of the pipe increasing the diameter, and was used for the purpose of facilitating welding and keeping the interior diameter of the pipe the same by use of a ring inside of the weld. We priced for the State of Illinois single bell end pipe instead of pricing it as of the same quality as that used in Oklahoma because that is the kind of pipe that was used by defendants in the State of Illinois. We are reproducing the cost of the same kind of pipe that is in the pipeline in Illinois and in all other states and other compressor station locations. It appears that in the State of Illinois the unit cost of pipe is 3.5734 dollars per foot as against 3.6463 dollars in the State of Oklahoma. There are elements involved in this buildup of the cost of 3.5734 dollars per foot that go to increase and decrease the cost. For example, this pipe that is known as single bell end pipe costs more per foot, or per ton, than the plain end pipe, so that the price of the pipe f. o. b. mill is higher than the pipe that was listed for the State of Oklahoma. The freight rate in the State of Illinois is lower than it is in the State of Oklahoma due to its being much closer to the mill. There is no sales or use tax applicable in the State of Illinois for this type of material. Other items that go to vary this price are differences in labor costs, differences in the actual labor performance due to the different terrain, the different type of soil, and the factors encountered in laying and lowering and stringing the pipe. In other words, there are differences in the man-hours required to perform the work and differences in the labor rates applied to those man-hours. In each instance we gave effect to the actual cost of reproduction as we found the facts to be in the particular state where we are reproducing the pipe.

934 Each line of our summary beginning on page 8 and continuing through page 64, with the exception of page 39, is supported by detail in other portions of the exhibit which are readily found by account numbers and by the index shown on the page preceding page 1 in exactly the same manner as is the detail found in those items which I have discussed here by way of illustration.

The amounts set out for each account number indicated on page 1 are, in my judgment, a reasonable and accurate listing of the reproduction cost of the property included in the several accounts, based on prices as of June 1, 1939, and prevailing in the locations where the property is situated. I am now referring to these accounts 1004 to 1024, inclusive. The figures I was referring to were those set out in the column "Reproduction Cost New". In the second column on page 1, under the caption "Present Value", are set out the figures resulting from the subtraction of the depreciation figures furnished us by Mr. Biddison from those reproduction costs to which I was referring in the last two or three questions.

Cross-Examination by Mr. Booth.

I had nothing to do at all with the determination of the existing depreciation which was made by Mr. Biddison. The only work I had to do with the depreciation as listed in this report was the mathematical work of subtracting Mr. Biddison's depreciation from our reproduction cost new. That is true of the other members of our organization. They had nothing to do with the determination of the existing depreciation.

Cross-Examination by Mr. Slaff.

I will prepare a list of the cases in which I previously testified, with the dates on which I testified.

935 **FRANK W. STODDART, a witness for the defendants, testified:**

(September 1, 1939)

Direct Examination by Mr. Morgan.

My name is Frank W. Stoddart. I can't say definitely where I live because I am part of the traveling organization of Mr. Hamilton, and am usually on the road. My office, when I am at the office, is that of Mr. Hamilton in New York.

In 1925 I graduated from the College of Engineering at Iowa State College and received a bachelor of science degree in mechanical engineering. Immediately upon graduation in July of 1925 I was employed by the Cities Service Company and went to Denver, where I entered the employment of the Public Service Company of Colorado as a junior engineer in their training school. That was a training school designed by the Cities Service organization to train employees for future positions in their organization. I remained in the employment of Public Service Company of Colorado for approximately one and one-half years.

On the completion of my work there in December of 1926 I was assigned to a regular job with the Doherty organization. During the training period in Denver I was assigned to a special job in the fall of 1925 in the city of Fort Collins, Colorado, where I worked for the Colorado-Wyoming Gas Company. I was employed in the first place to do certain design work on a natural gas line which they contemplated laying from the Wellington Dome, near Fort Collins, to the cities of Fort Collins and Cheyenne, Wyoming. While there, I made all of the maps from the surveys of that line, designed various items going into the line such as gate fittings, drips, meter settings, buildings, and so forth, drew all of the plans for this, drew up bills of material for this work, and after work was commenced on the construction of the line was retained by that company as a welding inspector on the portion of the line running into Fort Collins.

My next assignment was at Joplin, Missouri in the employ of Empire District Electric Company with which I remained for a period from December, 1926 until about March, 1929. I was employed as a power sales engineer in the lead and zinc mining district of southwestern Missouri, southeastern Kansas and northeastern Oklahoma.

In March, 1929 I was transferred to the New York office of Henry L. Doherty & Company, where I was employed in the rate and valuation department under F. C. Hamilton, with whom I have been associated ever since that date in rate and valuation work.

I am a member of the American Gas Association and at times I have represented Mr. H. D. Hancock, who is president of Gas Advisers, Incorporated, on rate committee work for that organization. Gas Advisers, Incorporated, is a mutual service company, similar to Electric Advisers, Incorporated.

936 Ever since my employment with Mr. Hamilton I have been engaged more or less in valuation work. I have prepared numerous valuations, in some cases working alone and in others with assistants. This work has been on oil marketing properties, which the company contemplated buying, and on natural gas pipeline systems. In 1931 and 1934 I assisted in the work of preparing a valuation of the Cities Service Gas Company. During quite a portion of that time I actually had supervision over crews in the field making inventories and crews in the office pricing that inventory and preparing it for presentation. I worked also on the property of Republic Light, Heat and Power Company, and Northwestern New York Gas Company, preparing a valuation of those properties for presentation to the Public Service Commission of New York. More recently I had active charge of work on the valuation of the Empire Pipeline Company, which is an oil pipeline having property in Kansas and Oklahoma and in the East Texas field, for presentation last year before the Interstate Commerce Commission.

In connection with valuation work, I have done some special work in the nature of pipe tests on pipe samples taken from pipelines in the Mid-Continental area. In other words, that testing was made for the determination of corrosion in pipelines and my work consisted not only of inspecting the pipe in the bell holes, but also of testing coupons, taken from sections of that line that had been removed, in the laboratories of the University of Kansas, and I have also made numerous burst tests on pipe in the shops of the Cities Service Gas Company. These were hydraulic burst tests.

I have never appeared as a witness in any proceeding before. I have had to do with the preparation of the valuation studies that are being presented here on the properties of defendants. I have been actively engaged in this work both in 1938 and in 1939, which is embodied in Exhibit 125.

I was not in Chicago during the entire time that the organization has been working on these studies because it so happened that the hearings before the Interstate Commerce Commission were being conducted during that time and I was here in Washington quite a bit of that time. I did spend the major portion of the time in Chicago last year and I was in Chicago during the entire time we spent on this work this year. I was assigned for special attention to the specific job of determining the reproduction cost new of the gas wells owned by Texoma Natural Gas Company.

On June 1, 1939 that company actually owned the physical property in 159 wells in the Panhandle field. I took or caused to be taken under my direction an inventory of all the physical equipment used in connection with each of those 159 wells. I sent men into the field to make an inventory of all the top fittings, that is the portion above the ground that could be seen, which I personally checked in the field. I have been in that field and have personally checked those notes, and I also personally made and directed the inventory in the office at Chicago from the records of the company of all that material, and of other equipment that goes into the hole that cannot be seen in the field. It is impossible, of course, to see anything below the surface of the ground in a gas well.

937 These wells are not all alike in the sense that they have exactly the same number of strings in the casing and the same length of casing strings. Each well is a problem of its own. In other words, the depth of the wells will vary, depending upon the depth of the sand, the sizes and lengths of the strings in the casing of the well, etc. So each one had to be figured out as an individual. We cannot look at a well and tell how deep it is.

We ascertain the facts concerning those features of the wells necessary for our information in the cost of reproducing them, which are not visible above ground such as the quantity of casing, the quantity of cement used, the depth of the well, and other things that may be hidden or invisible about a gas well, from the records of the company. The company keeps a very accurate record of what goes in. They keep what is known as a well log, which describes the depth of the hole and the amount of material and kinds of material that went into that hole, and these records were available to me at the Chicago office. The facts utilized in calculating these reproduction costs as to those items which are not determinable from the surface were taken from the records of the company, including the well logs kept by the company. The strings of casing that I have assigned to each well are the actual strings of casing which are in those wells at the present time. If a well has three strings of casing I reproduced it with three strings of casing. If two or one, I reproduced it as having the exact number of strings that it actually has. The casing of all of Texoma's wells is cemented, and I ascertained from the records of the company the number of sacks of cement that was used in cementing the casing in the well and ascertained the cost of placing that cement at the bottom of the casing. I ascertained also the cost of the cement delivered at the well and the cost of putting it into the well. I drilled these wells to the exact depth to which they were actually drilled. In other words, we reproduced these wells exactly as we found them on June 1, 1939.

According to the index in the front of the exhibit, these wells will be found in the detailed summary in volume 1 of Texoma Natural Gas Company on pages 41 to 54, inclusive of the detailed summary. The first column in the detailed summary entitled "Reproduction Cost New" represents what I have calculated in the details as the reproduction cost new for each and every well owned by Texoma Natural Gas Company. They are listed by wells, and the amount of money found opposite each well is the reproduction cost new of that particular well. The amounts cannot be uniform due to the variation in the depth and size, the amount of casing in the well, etc. The first well listed is the L. A. Aebersold well, which may be found on page 568 of volume 2 of the exhibit. The first item on that page is headed "Casing". This is seamless casing, 8¼ inches in diameter and 32 pounds per foot. The quantity of this casing in the well is 2,487 feet, which I have priced at 1.8026 dollars per foot, making a total of $4,483. I arrived at the amount by multiplying the quantity by the unit cost. I took 2,487 feet as the quantity of casing because that is the amount of casing that I found from the

records to be in that well. I arrived at the unit cost of 1.8026 dollars in the following manner. That cost first contains a price of 1.4678 dollars per foot f.o.b. Lorraine, Ohio, for the casing material. That price was secured
from the manufacturer of the casing as we sent him a
938 letter requesting quotations on that type of casing and
this is the price quoted. That is an f.o.b. price from which we have subtracted 2%, the cash discount applicable to all casing. This reduces the price to 1.4384 dollars per foot. To this amount I have added freight from the mill to Texas in the amount of .2784 dollars per foot, which gives us a delivered cost of 1.7168 dollars per foot at the warehouse in Texas. All material going into the well passes through a warehouse, and the cost last stated is the cost to the warehouse. These companies generally buy quite a large quantity of material anticipating a certain number of wells to be drilled in the future, and put that material in the warehouse rather than on the lease, so it can be looked after and will not be stolen. To the cost in the warehouse I have added a warehouse charge amounting to .0858 dollars per foot, which, added to the delivered cost price, brings the total cost to 1.8026 dollars per foot, the unit cost I find on page 568 of this exhibit. That warehouse charge was worked on a percentage basis, based on all material going through the warehouse. That is partly a labor cost of tallying and handling charges, and of course there are certain fixed costs of the building for house material that have to be considered in that cost. In computing the reproduction cost of the item "Casing Clamp" I found from the records of the company that there was one set of casing clamps on this well. This is due to the fact that there is only one string of casing in the well so only one clamp was needed. I have priced this one set of 8¼ inch casing clamps at $15.27. I arrived at this price in the same manner that I arrived at the price of the casing in applying those factors that were applicable to it. In this item, and in many others in the exhibit, the totals are stated in terms of even dollars. I do not give effect to the 27¢ in the cost of the casing clamp, but treat that cost as $15. If the cents are less than the half, I throw them out, and if more than a half dollar I give it the dollar above. They will average out in the long run by totalling dollars. That is the uniform plan of organization in this exhibit. I arrived, of course, at the number of casing shoes and the number of lots of top fittings in the same manner that we

have done in all the others, that is, we used the actual number found in the particular well under consideration.

We come now to the item "Contract: Drilling—rotary tools—2,685 feet" at a unit cost of $3.25. The log of the well shows that when this well was drilled the contractor actually drilled it to a depth of 2,685 feet and was paid on that basis. All contracts for drilling are made on a per foot basis. We arrived at $3.25 per foot after sending out to several drilling contractors in that area requests for quotations on drilling, and that is the quotation we received from them for drilling in that particular area. I checked that with the contract price per foot which the company was paying currently as of June 1, 1939. The company is now engaged in drilling some wells and I found that the prices I have used here are identical with the drilling rates now being paid by the company. The contractor's contract calls for the drilling of a well to a specified depth and when that depth is reached his contract is completed and he is paid on the basis of the number of feet he has drilled. However, if after the drilling is completed certain cleaning out of the hole is necessary around the well which requires the contractor's time, he is paid for that additional time on a day basis. As a matter of fact, in the drilling of a gas well, it is often necessary for the contractor to be retained there with his tools until the well can actually be put on production after he has completed his work. I find occurrences like that in the records of the company. The amount I have used here I found by analyzing the drilling costs of a number of wells that have been drilled within the past six months or a year. They are not uniformly retained for one day. There is a
939 variation according to the records of the company. I found in certain cases that no day work was required of the contractor, and in other cases I found as many as five or six days required of the contractor. In order to reproduce this I could not tell what the hazards would be after drilling each and every well, so I have used an average figure which represents the average amount that the company would have to pay the contractor for extras. This one day is the average per diem payment which the company has paid on its wells as a whole, according to the records. I have used an average of one day for each well instead of undertaking to set out in each instance just the number of days that the contractor was held on each particular well. I did this because in reproducing these wells

it would be impossible for us to determine what hazards they would run into on each and every well. We do know those hazards exist, and in the past the company has paid this average amount for extra work. The $90 figure is the amount actually paid to the contractor as a part of his contract price for doing this work. This $90 covers 24 hours' work with his rig equipment and tools. That is contractual rate per day just like the drilling and the work that goes with the drilling is contracted on a per foot basis.

Questions by the Examiner.

I have applied that one day uniformly, but I think there are some wells where I have applied more than one day. I think there are some wells where I have applied more than one day. For instance, there are one or two wells in here that have been acidized, and I think one or two wells that were shot, and of course after acidizing or shooting a well, there is a certain amount of cleaning up to do, which the company contracts to the contractor, and whenever that exists I have determined how much extra day work is necessary for cleaning out the hole. For instance, the R. S. Coon well on page 598 shows nine days. In the second line below "Day Work" you will find an item of "Shooting Well." I determined from the records of the company that in shooting the well there would be an additional 8 days necessary for cleaning out the well after shooting it, in addition to the other cleaning out which would be covered by the one day. This 8-day special item of Day Work is very close to the actual time required as reflected by the records of the company. I did not arrive at it exactly in that way, however. When I asked the contractor for a quotation on shooting the well I also asked him in that letter to tell me how many days would be necessary to clean out after he had completed his work. This cleaning out would have to be done by the contractor and not by the shooter. I took this 8 days from his letter stating that so many days would be required to clean out the well after the shooting. I do not mean that the man who shoots the well would clean it out. There are two operations. One contractor would shoot the well and then the contractor who drilled the well originally, who is an entirely different contractor, would clean out the hole.

Direct Examination Resumed by Mr. Morgan.

If the shooting was done at the completion of the well, the original contractor would be kept there until the well could be shot and then he would go in and clean it out. This is a charge for keeping his equipment on the job and cleaning the well out after the shooting has been done. This 8 days is the time that we were advised by the man who did the shooting would be required for the contractor to clean out the well and condition it after he had administered his shot.

940 The reason I did not use the actual figures in this instance is due to the circumstance that some of the wells of Texoma were purchased at the time the company was organized and they do not have complete records, although we did receive from the companies that sold them the wells the log showing the depth of the wells, the amount of casing in the well, etc. We could not determine all the costs from those old records. In other words, I have tried to predicate my costs on wells being drilled currently. I applied this day work to all the wells, using an average figure. I averaged some of the wells which had not been cleaned out with some wells which had taken six or seven days to clean out and found that the average was one day for all wells. In other words, I was trying to arrive at an average cost that I could apply to some older wells that I had no records on.

These older wells on which we had no records as to such costs were wells that were drilled prior to being acquired by Texoma. We had no difficulty in finding records for the wells drilled by Texoma. I applied this one day of extra work in some cases to the wells Texoma itself had drilled because I took an average for all wells and in the long run it would average out.

"Cementing" I have included in the amount of $350 for each well. This is the actual amount paid by the company at the present time for cementing wells. In other words, a cementing job requires 125 sacks of cement which is put in the hole by the contractor, and the cost of putting it in the hole is the contract labor, so that is a uniform amount. I base that amount on what the company was paying currently as of June 1, 1939. The company is currently paying $350 for the material and labor of placing the cement in the well.

The next item, "Rig Expense", amounts to $1,099. This rig expense includes two or three items mainly. It includes first, the cost of erecting the rig which is done by the contractor. The company actually furnishes the rig for drilling the well, but it does not attempt to erect it itself. It contracts the erecting of that rig. It is a steel rig and has to be put together on the site, so the company contracts for the erecting and dismantling of the rig. That is a fixed amount which I have determined from the records of the company amounting to $750, and to this amount for drilling a well with rotary tools I have added an amount of $349, which I have determined is the expense to the company for the rig which they own and furnish to the contractors. In other words, there is a certain amount of depreciation on that rig, certain fixed charges that have to be charged into each well, and this amount I have found to be $349. I have determined the amount and put it in here because it is properly chargeable to each well. I don't know just how they handle it, but I have determined the amount of expense that they are put to for drilling wells. It is not reflected in the job order for drilling the well.

In that connection I took into account the number of wells that would have to be drilled, and the period during which they would have to be drilled, in order to reproduce this property as a whole during the period of construction that we have used here in this study. I have assumed that all of these wells would have to be drilled in approximately one and one-half years, which was the construction period for the building of the entire system.

941 I determined that if all these wells were to be drilled in this one and one-half year period, they would have to have eleven rigs drilling at one time—continuously drilling throughout the period in order to drill all the wells in the specified time. I have just allocated to each one of the wells its proper proportion of the cost which would have to be incurred in connection with providing these rigs. These rigs are a very essential part of the process of getting these wells drilled.

You will find under "Contract—drilling" on page 570 that this well was drilled with cable tools whereas the wells on pages 568 and 569 were drilled with rotary tools. The fact that this was drilled with cable tools required additional expense in certain materials furnished by the company. In addition to the derrick unit they also furnished a bull wheel unit, a band wheel and walking beam unit, machinery supports, and so forth. There is additional investment involved in wells drilled by cable tools. Thus the cost corresponding to $750 and the $349, totaling $1,099 set out in the analysis shown on pages 568 and 569 must be changed to $1,272 in the case of the wells shown on page 570, in order to meet the actual cost of this cable tool type of rigging. This is the amount arrived at by allocating to each well its proportion of the total additional cost of drilling the number of wells that were actually drilled by cable tools. Those items shown on page 570, amounting to $351, $199 and so on down through the remainder of the column, are not dependent upon the depth of the well or the amount of casing in the well, but are miscellaneous expenses incurred in the drilling of the well and are generally uniform expenses for each well whether drilled by a rotary or by cable tools. I arrived at those figures by analyzing the actual costs of drilling the number of wells during the last 12 months, and have arrived at certain average costs for these items. In analyzing these records of the company I was able to break down into the component parts all of these items, and I found that they varied slightly from well to well, but in order to apply these present-day miscellaneous costs to the older wells, I had to take averages for all of these items, and these are averages which represent actual present-day miscellaneous costs for drilling wells. All these costs are actually incurred and paid and the company's record so reflect. I found that the total cost of reproducing the well referred to on page 568 is $17,008. By referring back to page 41 of the detailed summary under the column headed "Reproduction Cost New" we find that amount to be the first item in that column. On page 41 there is the figure $850 immediately to the right of the $17,008. That figure is in the column headed "Depreciation Deducted" and is the amount of money which was determined by Mr. Biddison and represents his figure for depreciation to be deducted from the reproduction cost new of this well. This leaves a net, after the subtraction of the depreciation from the reproduction cost new of $16,158.

These varying amounts set opposite the wells listed, beginning on page 41 and extending through to the middle of page 54, were arrived at in exactly the same manner as were the amounts $17,008 and $16,158 to which I have referred.

For the purpose of further illustrating the way we arrived at those figures, turn to page 569. We have some five

different kinds of casing listed in that well as against only
one string of casing, all of the same kind, in the well set
out on page 568. I have shown here the exact amount
942 of casing which the books of the company show to be
in that well. In other words, I find that even in the
case of rotary drilled wells, there is more casing in some
wells than in others. In the case of cable tool wells there
is sometimes more casing than in the rotary well. In each
instance we reproduced the exact amount of casing that
is found in the particular well.

From my study of the total number of wells, the way those wells were drilled and completed, the way they have been equipped, and the condition in which I have found them equipped as of June 1, 1939, and in the light of my investigation and that of our organization as to the material prices, labor costs, and other elements which we have figured in the unit costs applied to the material in those wells, it is my judgment that the figures set out in detail from page 568 to the middle of 726 represent the reasonable and actual cost of reproducing those wells if they were to be drilled beginning as of June 1, 1939.

These costs are carried back into our detailed summary beginning on page 41 and continuing through succeeding pages, in the column headed "Reproduction Cost New," and these figures set out in the third column under the caption "Present Value" represent in my judgment the reasonable cost of reproducing these wells new as of the time we have just mentioned, less the depreciation as determined by Mr. Biddison. The figures shown in the third column under the caption "Present Value" on page 41 and succeeding pages to the middle of page 54, represent the amount left after deducting the existing depreciation as determined by Mr. Biddison from the reasonable cost of reproducing those wells as of June 1, 1939. This represents the present value calculated by deducting the depreciation as determined by Mr. Biddison from our reproduction cost new.

These depreciation figures are not my figures. I merely recorded them on the sheet, subtracted them from the reproduction cost new, and arrived at the figure in the third column. I think the subtraction is correct.

Questions by the Examiner.

Under the terms of the drilling contracts I read, they provide for a fixed sum per foot, with a provision for an additional sum if the driller runs into difficulties. The additional sum is an amount for the time necessary for him to work on cleaning up the job. If it takes ~~him~~ 1 day, it is so much money, and if it takes him 2 days, it is so much money. It is all stated in the contract at so much money per 8-hour shift.

Direct Examination Resumed by Mr. Morgan.

I have all the work sheets showing the details used in the preparation of the figures submitted in Exhibit 125. These work sheets and supporting data will be available to counsel and engineers of the two commissions.

943 I can't say whether the provision for paying the contractor for extra work is part of the contract for drilling the well, but it is paid on a per day basis. The trouble which usually causes the detention of the contractor after the actual drilling is completed is usually due to something that gets into the drilled part of the well such as the caving in or bridging of the formation after the well has been drilled, and the footage obligation completed.

Cross-Examination by Mr. Slaff.

The reason that in some places we use $4 per foot as the unit cost for drilling while in others we use $3.25 per foot is due to the fact that the drilling rates vary from county to county. Drilling contractors have established prices for various parts of the field, due partly to the fact that water is hard to find in some places and there they charge more per foot, and so on. It is an actual contract price and is the amount that is actually paid by the company in various parts of the field. Texoma is actually paying $4 per foot right now for the drilling of some of their wells. In Moore County the wells are drilled deeper than in Gray County, and the depth of the well tends to slow up the rate of the drilling under some circumstances. It takes longer to drill out the last part of a deep well, and they charge more for it. There are three unit costs per foot used in the exhibit —$3.25, $3.50 and $4. In Hutchinson County we find that it is $3.50.

Questions by the Examiner.

We furnished the contractor with information showing the depth of the well and the amount of casing in the well, and told him in which county the well was to be drilled, and he quoted his bid price on the basis of that information. He would bid the same way on a well if we were actually going to drill it today, on the basis of that limited amount of information. He is very familiar with the field, and by knowing in which county the well is to be drilled, he is familiar with the depth of the sand; he is actually drilling wells there today; and can readily make a bid on drilling a well in that area.

944 F. C. HAMILTON, recalled by defendants, testified:

(September 1, 1939.)

Direct Examination by Mr. Morgan.

When my organization was arriving at the cost of various materials and equipment which would be required to reproduce this pipeline, I personally took the responsibility of determining the proper cost to be applied to the pipe that would be required. I did this for the simple reason that I have had an opportunity to familiarize myself with purchases of pipe for a great many years. Beginning back in 1918, I made an original cost study of the Republic Light, Heat & Power Company property as it is now constituted in and around Buffalo, New York. That property contained some of the earliest gas lines that were laid. In our New York office we have some paper weights that were made from the lead pipe that led to a flare in Fredonia, New York, at the time of Mr. Lafayette's celebration. Some of that pipe we have in the museum in New York, and there also came out of that district some wooden pipe made by boring holes through logs which were longitudinally fastened together with what we guess to have been Civil War army blankets covered with tar and joined on each end to the wood with steel straps. That particular line was laid by the Bloomfield and Rochester Natural Gas Company. It was laid in 1870. I cannot recall the name of that old company that laid the lead pipe because, of course, we were not familiar with it. In that original cost study, of course, we found a large portion of cast iron pipe with two types of joints, oakum and tar or yarn and lead joints. Later we found, as time went on, more wrought iron pipe. Then there was developed finally the steel pipe in the form of lapweld pipe. We have available in our office those records up to 1918 from that original study as to what those various types of pipe cost. I am eliminating the lead and wood pipe, of course.

That original cost study was presented to the New York State Commission, to the Bureau of Capitalization, for the purpose of the authorization of the securities on the consolidation of several companies which are now represented by the Republic Light, Heat & Power Company.

About two years ago we were requested to bring up to date from 1918 the cost of the property which had been constructed there since that time, and reclassify all of it under the new classification of accounts put out by the New York Public Service Commission. Yesterday, at Albany, two of my men presented the entries for approval on that work, so we have the history of that company from the beginning, back in 1868, on down to date.

At the present time, in anticipation of the order of the Federal Power Commission putting in the new classification of accounts for natural gas pipelines, I have had men working for a period of nine months on the Cities Service Gas Company's records and the records of the predecessor companies that now constitute the Cities Service Gas Company. The tentative classification of accounts has been put out and has not been made final, as far as I know, for natural gas pipelines, but is expected to be made effective as of January 1 of next year. That work on the Cities Service Gas Company's records has developed costs of
pipe beginning in 1904, which was when their first line
945 was laid by the Kansas Natural Gas Company. That
has all been available to me. That first line laid by the Kansas Natural Gas Company was 16-inch plain and lapweld, 20-foot length pipe weighing 43.168 pounds per foot. The price of that pipe f.o.b. Pittsburgh at that time was $58.20. I just cite that to show where some of the information that I have been able to acquire comes from.

In addition to that, I have been engaged in the valuation of large gas pipeline and gas distribution companies for many years, and on the occasion of each valuation I have had to secure quotations for pipe. Naturally, I checked those quotations each time against purchases of pipe which have been made by the company in periods prior to our determination of the cost of reproduction.

During a long period, from 1925, I was on the executive committee of Henry L. Doherty & Company, to whom was submitted the operating budgets of the subsidiaries of Cities Service for each year. Those operating budgets included their construction programs and necessarily included their estimates of cost of construction. Because of my department's work and familiarity with prices, questions as to the adequacy of the estimate of such items of construction as pipelines were submitted to me. From about 1924, I have had a man in my office who has done very little else except keep a continuous index of prices of the various items that enter into the construction of natural gas pipelines and of electric and artificial gas utilities. I, of course, made available to him for his assistance all of the information which was gathered in the way of quotations, and by checks on costs that had been paid by operating companies where we were making valuations. Also, I have had to do, in a responsible way, with the approval of construction projects on which, of course, estimates of the cost of construction based on quotations had been submitted.

Because of the fact that so much of the cost of defendants was dependent upon the price of the pipe itself, roughly some $14,000,000, I felt that it was necessary, in collaboration with Mr. Eastman and Mr. Willard, to spend considerable time on the accurate determination of what should be the proper cost of pipe. That could easily be determined if the amount were small, because you would pay what is shown by the current standard discount sheet plus an extra 10 per cent discount for quantities, but when you run into such enormous quantities as are shown in this valuation of one particular size, for instance of the 24-inch—there is in this system about 214,000 tons,—when the quotations came in, the quotations on the 24-inch showed that they had given all of the discounts in their quotation that appeared on the standard discount sheet, and that they had taken off 10, 10 and 5 per cent, approximately, in addition to the regular discount sheets that you might expect with reasonable orders. When it came to the smaller quantities in the other sizes, they had not quoted nearly so desirable a price. They had quoted more in line with the prices that would be expected to be given for the quantities of those particular sizes that were shown in our requests. In our

requests for quotations we had asked for a quotation on the quantity that was shown in the inventory. For instance, they quoted prices on the 16 and 12-inch pipe as if those were the only pipe purchases involved. This was also true of most of the smaller sizes of pipe. They had not done that on the 16-inch because there was a very considerable portion of that, but on most of the smaller sizes that is what they had done. I felt, and I still feel, that a purchasing agent who has in his hands an order for such a large quantity of one size could hammer the pipe manufacturers into giving him the same quantity discounts
946 on those quantities of smaller pipe, notwithstanding
there were not sufficient quantities of that smaller pipe to justify such a discount.

Those quotations on the large size pipe were $62.35 a ton f. o. b. Gary for electric weld and $60 a ton f. o. b. Lorraine for the seamless 24-inch pipe. By interpolation we found what seemed to be the additional deductions that they had given over prices that were available to the public and to pipelines in general, and then we applied the same additional discounts to all of the rest of the pipe on the system.

They had done one more thing in this situation on these bids. The standard discount sheets apply to lap weld pipe. There is, and there has been for many years, a fixed addition per ton, after the standard discount of $2 for electric weld and $3 a ton for seamless. In these quotations they omitted those additions from the standard discount sheets and then still applied the discounts which I have listed. That is generally what we did and as a result that has lowered the cost of the 24-inch pipe in this system below what the company paid for it when they did have this tremendous order in their hands by about $1,725,000. The 24-inch pipe, in other words, is in here, so far as the pipe itself is concerned, at $1,725,000 below what the company actually paid for it. I was familiar with this company generally at its inception. I knew about the preliminary work that was done on this, and I do know that we all felt when they made their original purchases of such a large quantity that they had reached what then was an all-time low for the purchase price.

Question by the Examiner.

The manufacturers' discounts were all based on lapweld pipe. The base price is always $200 a ton. That does not change. They issue changed discounts that apply to different sizes, and always apply the discounts to lapweld pipe. We will say that the discount for a particular size is 60 per cent, then your price would be $80 a ton for lapweld. If you want to order electric weld instead of that then the price would become $82, and if you order seamless the price will become $83. In other words, those additions are not subject to the discounts; they are added after the discounts are taken off. But in this particular situation they apparently not only gave the additional discounts to the companies but left off the additions for seamless and electric weld that had hitherto been put in.

Direct Examination by Mr. Morgan Resumed.

The net result, covering all of the pipe, as between the prices quoted and the prices we used here is a very considerable reduction below the original cost. I computed it only on the 24-inch pipe, because I had that tonnage available, but in the prices per ton the reduction on the other sizes below the quotations which we received, and below the prices that were paid originally, ran all the way from $2.30 per ton to as high as $30.40 a ton, according to the particular size and the particular purchase. As to the comparison between the prices quoted in response to our letters and the prices we used in Exhibit 125, the prices on the 24-inch are identically what they quoted us because they were quoting on that large quantity. The prices on all other sizes were less than they quoted us. I have examined that exhibit and I have been in contact with the work both this year and last year so that I am thoroughly familiar with what is in that volume. It was prepared under my direction.

947 Taking into account my experience in valuation work, my knowledge of the costs involved of the materials utilized in the construction of this pipeline, and the other costs incident to the assembling of its physical parts into a pipeline system, and in the light of the investigations that have been made concerning time hours, labor costs, and all of the other elements that have been mentioned here by me and other witnesses, it is my judgment that the amounts stated in this exhibit and summarized on page 1 of this exhibit, constitute in their aggregate the reasonable amount that would be required to reconstruct or reproduce this pipeline, if constructed as of June 1, 1939. (Objection by Commission counsel.) In my judgment it represents the

lowest price at which the property could be reconstructed at that date, with a reasonable construction period allowed. That construction period I have assumed to be the same period that was covered by the construction of the pipeline in the beginning. That study includes all of the physical properties of the two pipeline companies with the exception of the leaseholds.

Assuming the existing depreciation to be as stated in the figures furnished to me and my organization by Mr. Biddison, the figures in the second column set out on page 1 under the caption "Present Value" represent the lowest cost at which these pipeline properties could be reproduced after deducting Mr. Biddison's figures for depreciation. I have already stated that the figures set out in this exhibit have to do with the reproduction cost new less existing depreciation furnished by Mr. Biddison of the inert physical property. By the term "inert physical property" I mean that it was a collection of the material and equipment into a pipeline, so far as the physical property alone was concerned, and that it included no cost for seasoning the line, preliminary operations after the completion, and no cost for attaching business and making it an operating organization or building up a force to operate.

By "preliminary operations after the completion" I mean such operations as are necessary in the process of seasoning and tuning the plant up after it has been completed. There are always incidental costs involved in these early operations.

In addition to the value of the inert physical property, as I have defined that term, there is, as to this particular system, a going concern value.

By "going concern value" I mean a value to be assigned to the property over and above the cost of its physical property because of the fact that it has made the necessary expenditures and sacrifices to get a business attached, and that it has this business attached and has built up the income and is a going concern. Those costs, of course, come after the construction of the pipeline and are something that create an item of value. In other words, this pipeline without customers and without business is something entirely different from this pipeline that does have customers attached and is doing business, with its organization seasoned, familiar with their jobs, and with the resulting low operating costs that you get from that kind of organization.

At the request of defendants I have undertaken to analyze and determine from the records of the companies what the costs and the sacrifices of building the load and making this business a going business or going concern have amounted to in terms of dollars.

948 First I had, as did some of my older men, a quite intimate knowledge of the original cost of this property and the things that had to be done to get its business established. I considered it as an integrated project because the two defendants are interdependent.

In the first place, these costs for attaching business on this property are lower than could be secured by any pipeline with which I am familiar. The reason for it is this: It is a single pipeline from a single field to a market that has a potential use of many times the capacity of the pipeline, so that the cost of securing a sufficient load to fill the pipeline would be less than would be the cost of securing a load for a pipeline that was built to supply all of the ultimate needs of the whole district.

One of the reasons for this lower cost is this: In any town where the sales of gas are quite universal in all homes for cooking, water heating and house heating as they are in towns in Kansas, Missouri and Oklahoma, the average investment of the average domestic customer in equipment, by actual inventories which I have made, runs to roughly $135 per customer. When I say that I am giving you the average of the numbers of poorer homes and the smaller number of large homes. It is an average for domestic customers based on inventories of all of the equipment in all of the houses in town, and applies to domestic customers only.

When we run a pipeline to a town which has not had natural gas we start out endeavoring to sell gas to supplant other services which those customers have had, maybe coal, maybe oil, in some cases wood. Assuming that our gas rate is comparative, we still are up against the reluctance of the customer to throw away his investment in whatever equipment he now has and which he has bought for the purpose of utilizing the fuel which he did use prior to natural gas. In Chicago, because they were not building a pipeline of the size to supply all of the customers with all of their needs, they could get customers who were less reluctant. In other words, their time of attaching load would be less than it would have been were they building a pipeline to get all of the load that is there available.

I have made a study of what those items of developing and attaching business would cost in the case of this pipeline. I might add again that it was not built for the ultimate load, but it comes as near being a 100 per cent load factor as any pipeline with which I am familiar. You could not secure such a desirable load factor, if you were trying to supply all of the needs for heat of all of the customers in Chicago, or of any other town that I know of.

The business of any natural gas system fluctuates from month to month because of climatic variations which affect the sales to the domestic customers, and because of the variations of the seasonal needs of the industry. We have adopted, for the basis of these computations, the sales in the year 1936 of $14,537,985, for the year 1937 of $15,546,451, and for the year 1938 of $14,456,899, and have averaged those, arriving at an average figure of $14,847,112. Those are the only three full years during which the pipeline has operated since it was fully loaded. So I have used as a basis the average of those three years. Now during that period the capacity of the pipeline was increased by the installation of additional compressor station capacity. The nominally rated capacity prior to that
949 increase was 175 million cubic feet a day. Today it is 210 million cubic feet a day. Both figures have been exceeded on particular days due to packing of the lines. I have therefore taken 175 over 210 as a fraction, and reduced by that ratio the $14,847,112 which constituted the average revenue of three years, with the result that I got $12,372,593 as the amount of sales that would have represented the ultimate capacity of this system prior to the increase in its capacity. In other words, if the line had been loaded from the beginning and had a capacity of 175 million, the revenue which could have been expected on the same load factor that has obtained during these three years would have amounted instead of $14,847,112 to the sum of $12,372,593.

Using this $12,372,593 as a basis of the revenue representing the full load capacity as it existed prior to 1936, I have made a tabulation to indicate the average non-productive capacity in each of the preceding years. In the year 1932 the revenue was $5,854,567, which represented 47.3 per cent of the productive capacity. In 1933 the revenue was $6,254,177, which represented 50.5 per cent of the productive capacity. In 1934, the gross revenue was $9,485,366, or 76.7 per cent of the productive capacity. In the year 1935 the revenue was $12,036,535, or 97.3 per cent of the productive capacity. In those various years, subtracting the per cent of load that they have from the load which they could expect, and which they did get, we have in 1932 non-productive capacity of 52.7 per cent, in 1933 of 49.5 per cent, in 1934 of 23.3 per cent, and in 1935 of 2.7 per cent.

It must be appreciated that in the construction of a pipeline system such as this it is economical to build a pipeline for the ultimate capacity for which it is designed at the time you first install it. I might give you this example, that in the first year of operation they had nearly 50 per cent of their ultimate capacity in the line. You cannot have piece-meal construction in the pipeline, because it would have taken an 18-inch line to have carried 50 per cent of the capacity of a 24-inch line, and the 18-inch line for rights of way, and many other items, would have cost the same as the 24-inch line. The pipe and labor costs of installation and trenching would constitute far more than 50 per cent of the cost of the same items for the 24-inch line, so that the economy lies in installing the 24-inch line. You cannot make a piece-meal construction of pipeline capacity with economy.

The participants in this project received mortgage bonds bearing an interest rate of 6 per cent for the majority portion of the funds which they advanced for construction purposes. They knew, as a matter of course, when they advanced these funds that a certain number of years would be necessary before the project could acquire a business that would allow the payment of their interest, or the payment of dividends on stock. Anybody familiar with pipeline operation knows that. They also knew that it would be necessary to spend a very large sum of money on sales promotion work, both directly and in the way of contributions to distribution systems for the promotion work of those systems, if they were rapidly to build up the load. The earnings of the system from 1932 to 1935, inclusive, were not sufficient to meet the bond interest, and the companies were forced to borrow to meet ordinary cash requirements. No dividends were paid. I have taken the interest expense which represents the interest on the bonds together with the interest on the Gulf note which was given for the acquisition of some of the property that is now owned by the
company. These interest payments for 1932 were
950 $3,666,350. For 1933 they were $3,625,079, in 1934 they
were $3,598,329, and in 1935 they were $3,474,732. To

the interest for each of these years I have applied the percentage that was indicated by the non-productive capacity computed from the revenues, with the result that 52.7 per cent of the 1932 interest expense amounted to $1,932,166; 49.5 per cent of the 1933 expense amounted to $1,794,414; 23.3 per cent of the 1934 expense amounted to $838,411; and 2.7 per cent of the 1935 expense amounted to $93,818. The total of these four items is $4,658,809, and represents the rental on money which was invested in idle capacity during the period of the acquisition of the business that they now enjoy.

Bonds, of course, would not have been salable at the inception of this property, and I felt that in applying the interest rate of six per cent that was paid for all of this money I have applied a rate less than would be required to raise money for a new project similar to this. I have taken those ad valorem taxes that apply to the property itself, not including income taxes and items of that kind, and have applied them in exactly the same way. The taxes paid in 1932 were $301,766; in 1933 they were $301,629; in 1934 they were $270,558, and in 1935 they were $289,193. Applying these same percentages that I used in the previous calculations, I have determined the amount of taxes paid through that period on property that was non-productive. These percentages result in $159,031 for 1932, $149,306 for 1933, $63,040 for 1934, and $7,808 for 1935, a total of $379,185.

A determination of the amount of depreciation existing in this system as of June 1, 1939, has been made by Mr. Biddison. He determined the depreciation existing on that date on the system as amounting to $2,866,758. For the purpose of this computation we have made the assumption that this depreciation occurred at a uniform rate throughout the 8-year period since construction. On this basis the annual amount of depreciation would be $358,345. By that I mean the depreciation that has occurred, which has not been replaced by maintenance or otherwise. Applying to this amount the ratio of the increase in capacity of the system due to installation of additional compressors I reduced that by taking 175/210 of it, arriving at a result of $298,621.

Taking for 1932, 52.7 per cent of this, for 1933, 49.5 per cent of it, for 1934, 23.3 per cent of it, and for 1935, 2.7 per cent of it, I arrived at the depreciation represented in the system today attributable as having occurred on the non-productive capacity during those four years, and it amounts to $382,832.

Certain expenses on a natural gas pipeline are fixed and do not vary in proportion to the quantity of gas handled. In other words, certain officers' salaries do not go up and down with the gas handled, and neither do taxes and other items. Certain other expenses do vary almost directly in proportion to the quantity of gas handled, and naturally during the development period these expenses are much lower than in subsequent years when the full capacity of the line is being utilized. Without making detailed analyses, we have considered that the general and administrative expenses, pipeline expenses and telephone expenses are fixed and that a certain portion of these expenses are properly attributable to the system's non-productive capacity.

I have, therefore, taken those fixed operating
951 expenses which were in 1932, $1,127,807; in 1933, $881,430; in 1934, $810,684, and in 1935, $882,028. Applying these same percentages for non-productive capacity to these amounts I have a total for the four years of $1,243,366. By pipeline expense I mean that pipeline expense as contained in the Commission's Provisional System of Accounts as opposed to compressor station expense.

Prior to any construction, in fact beginning in July, 1939, various market surveys were conducted by participants in the project, and these surveys were available to the companies at the time the actual construction of the project was begun. No part of the expenditures for these surveys is included in the tabulation of direct expenditures made for the purpose of attaching business.

During the years since the completion of the project the companies have made the following direct expenditures for the sole purpose of attaching the business which they now have. In the year 1932 they spent $86,105; in the year 1933, $219,149; in the year 1934, $889,060, and in 1935, $373,058, or a total of $1,567,372 for building the business up to full load. I will add here, for the purpose of comparison, the expenditures by the same department in 1936, 1937 and 1938, which amount to $16,371, $16,115 and $17,788, respectively. In other words, the expenses were cut down to a very minimum as soon as the load was acquired.

Included in the total of these expenditures which I have listed were contributions to the Chicago District Pipeline Company amounting to $187,131 in the year 1933 and $705,-

065 in the year 1934, which were made for the sole purpose of developing the domestic and house-heating business of those utilities serving the Chicago territory. In 1933 $749, in 1934 $160,243, and in 1935 $353,783, or a total for the three years of $514,755 was contributed to utilities operating outside the Chicago area for the purpose of developing their business.

It must be borne in mind that while these expenditures were being made by the pipeline company there were other large expenditures being made by the distributing companies for the purpose of attaching business, with the result that the other expenditures tended to help attach the business to the pipeline, but included here are only the expenses of the pipeline company itself.

I have summarized these items as follows: Rental on the money invested in the non-productive capacity, $4,658,809; taxes paid on non-productive capacity, $379,185; depreciation on non-productive capacity, $382,832; fixed operating expenses due to non-productive capacity, $1,243,366; direct expenditures for attaching business, $1,567,372, or a total of $8,231,564. These costs that I have shown do not include all of the costs of attaching business, and such costs as are here included are low because of the very favorable situation of this pipeline as compared with a pipeline designed and built to supply all of the heating needs of a particular town. There has been omitted from these calculations any costs incident to the seasoning of the plant, which costs always follow the beginning of service on any system of this nature, and neither has there been included at any place any costs for the assembling and training of the operating personnel.

Based on these actual out-of-pocket costs incurred in order to provide, because it was economical to do so,
952 facilities for the handling of gas in advance of obtaining the load of gas to be handled, and taking into account my knowledge of the history of this company and of the progress it has made and the volume of its business, the properties of these companies possess, in addition to the value of the inert or bare physical properties, a value of at least $8,500,000 in the nature of going concern value.

Cross-Examination by Mr. Slaff.

In referring to pipeline expense I was referring to the company's own accounts which it considers pipeline expense and which was taken from their books. It would not include pipeline maintenance expense.

Cross-Examination by Mr. Booth.

I was directed by the defendants in this case to prepare a reproduction cost appraisal of the property of defendants, that is the physical property of the defendants, exclusive of leases, and to prepare this appraisal based on the prices prevailing on June 1, 1939. I was directed by the defendants to deduct from this reproduction cost new the amount of existing depreciation which had been determined by Mr. Biddison. I do not sponsor in any way the amount of existing depreciation determined by Mr. Biddison. I have no connection with it other than to be responsible for the mathematics of deducting it from the cost of reproduction. In addition to that I, myself, prepared this study to which I have just testified, as to the going concern value of the property. That is all I was directed to do upon behalf of the company in presenting this case. I also prepared an appraisal based on 1938 prices but was not asked to present it in this particular case. All there is here is the 1939 appraisal.

Further Cross-Examination by Mr. Slaff.

I have a list of the cases in which I have testified but unfortunately the only dates I have are the dates that I was on the case from the beginning to the end. I cannot give you the dates at which I testified and will not be able to do that until I get to the New York office. I will have somebody get that up for me and get the exact dates.

Further Cross-Examination by Mr. Booth.

While I did not undertake to value the leases, as I have already stated, Mr. Eastman, in connection with his study of preliminary operations of the company, included the delay rentals paid on the leaseholds during the period of construction. That is the only way in which these leases enter into our study. We did, of course, include the wells, as explained by Mr. Stoddart.

953 (Document entitled "Texoma Natural Gas Company, Gas Well Details, Well Groups Nos. 1 to 12, Inclusive," marked Exhibit No. 118 for identification.

Document entitled "Errata Sheets for Exhibit No. 122," marked Exhibit No. 124 for identification.

Document entitled "Rate Reductions Effected by the Introduction of Natural Gas in the Communities Served by Natural Gas Pipeline Company of America," marked Exhibit No. 126 for identification.

EXHIBITS NOS. 118, 124 and 126 offered in evidence. EXHIBIT NO. 118 received in evidence without objection.)

954 P. McDONALD BIDDISON, recalled by defendants, testified:

Direct Examination by Mr. Hedrick.

(September 5, 1939)

At the time I testified in this case before, which was at Chicago, on August 3, 1939, I went into my educational qualifications and experience over the time I have been engaged in business since leaving school. I will add to that statement the experience I have had in making estimates concerning the existing depreciation in the various properties ordinarily owned by natural gas pipeline companies.

During the war and shortly after the close of the World War I had occasion to acquire pipe for construction purposes for gasoline plants in the State of West Virginia, and during that period I bought a considerable amount of used pipe because new pipe was almost unobtainable. I inspected a great deal of this class of material at that time to determine the purposes for which it was usable. Prior to that time, during my connection with the Ohio Fuel Supply Company and its associated companies, I had numerous occasions to examine oil well and gas well casings, to determine its suitability for re-use. About 1913 or 1914 I was required to examine and pass upon the condition for re-use of a considerable amount of natural gas lines which had been acquired, or were being acquired by the Ohio Fuel Supply Company in the south central Ohio gas field areas. I was required to determine how much of this pipe was suitable for re-use and for what purposes it could be re-used, and what portions of it would have to be junked. About

1923 I made inspections of natural gas pipelines and distribution lines in the vicinity of Camden and Eldorado, Arkansas, and Monroe and Bastrop, Louisiana, for the purpose of fixing the price upon properties for purchase by my then employers. In 1923 I made purchases of a large amount of used oil line and gas line pipe for the purpose of relaying in Louisiana. This material was acquired in Indiana and Illinois in sizes from 4-inch up to and including 12-inch. On this pipe I determined the purposes for which it was suitable to be used, directed the amount of rejections, and the amount of repair work on it, and put it in condition for use.

In 1936 I made the determination of the suitability for re-use of about 70 miles of 12-inch pipe lifted by the Lone Star Gas Company, determined the rejections, the repairs necessary to put the usable pipe in condition for re-use, and in that connection I made a rather detailed determination of the distribution of pitting on that pipe. Each joint of that 70 miles of pipe was inspected from end to end by men under my directions for the determination of the amount of pitting and the distribution of pitting.

In 1928, and again in 1936, I think it was, I made an inspection of the distribution properties at Fort Worth, Texas, of the Fort Worth branch plant of the Lone Star Gas Company, for determination of the condition of that property in a valuation. I have made similar determinations on the condition of pipe in distribution of plants for Galveston, Waco, El Paso, Wichita Falls, Sherman, Denton and Greenville, all in the State of Texas, and for a group of 33 smaller towns in Texas of the Community Natural Gas Company, and for a group of 26 smaller towns in Oklahoma for the Community Natural Gas Company.

955 In 1931 I made a determination of the condition of the transmission lines and compressor stations of the Cities Service Gas Company in connection with a valuation.

In 1932 I made a determination of the condition of the production and transmission lines and the general property of the Lone Star Gas Company located in Texas and Oklahoma in connection with a valuation. Again in 1933 I made a similar determination. I made a determination of condition of the production and transmission lines and general property of the Oklahoma Natural Gas Company in the State of Oklahoma in 1937.

I made a determination of the condition of the oil pipelines of the Empire Pipeline Company in 1937, in connection with a valuation made by others for presentation before the Interstate Commerce Commission.

I made a determination of the condition of the production and transmission lines and general property of the Arkansas-Louisiana Gas Company located in Louisiana, Texas and Arkansas in 1935 in connection with a valuation in which I was participating.

I made an inspection of the transmission lines of the Southern Natural Gas Corporation in the State of Louisiana in 1933, in connection with some taxation suits that were pending.

I made an inspection for the determination of the condition of the property of the Albuquerque Natural Gas Company in the State of New Mexico in 1935, in connection with a valuation as of the same period, for presentation in a case involving the application of the New Mexico statutes in regard to making common carriers of natural gas lines.

In 1936, I made an inspection to determine the condition of certain oil gathering pipelines in the East Texas oil field in connection with the valuation used for the consolidation of properties.

I made an inspection of the distribution and transmission lines of the Sapulpa Gas Company properties in and near Sapulpa, Oklahoma, in connection with the valuation which I was preparing. I have made inspections of the distribution properties of the Arkansas-Louisiana Gas Company for the determination of their condition in connection with valuations in Texarkana, Eldorado, Conway, Pope, and some other minor communities on that system, all in the State of Arkansas.

Those inspections to which I have referred cover property of the same general character as the property of defendants.

The published bulletin to which I referred in my testimony of August 3, concerning gasoline plants, was written by George A. Burrell and George C. Overhold, both at that time associated with the Bureau of Mines, and myself as co-author. It was a U. S. Bureau of Mines bulletin and was No. 120 and entitled "The Extraction of Gasoline from Natural Gas by Absorption Processes". This same bulletin was presented substantially as a joint paper by the same authors before the Natural Gas Association of America at Pittsburgh, about the spring of 1917.

956 I was requested by the defendants here to make an inspection of their properties to determine their physi-

cal condition. I made two inspections: One in March, 1938 and one in May, 1939. I have prepared a report of my findings in the form of an exhibit for presentation in this case.

(At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company—Valuation of Property—Deduction for Depreciation as of June 1, 1939, Witness P. McDonald Biddison". At the direction of the Examiner, the document was marked Exhibit No. 127 for identification.)

These findings are set forth in Exhibit 127 for identification. In general the contents of this exhibit are, first, a letter of transmittal and explanation, and following that on page 1 is a title page, on page 2 an index, beginning on page 4 is a tabulation of the condition of the respective items of property, the reproduction cost new of those classifications as determined by Mr. F. C. Hamilton in Exhibit No. 125, the amount of depreciation to be deducted from the reproduction costs new by virtue of the condition in which the property is found, and a column of present value figures which represent the remaining amounts after deduction from reproduction costs new of the amount of depreciation.

On pages 4 to 38 are included the property accounts and values as described for Natural Gas Pipeline Company of America. On pages 40 to 64, inclusive, are shown the values as described for the property classifications of Texoma Natural Gas Company. There is a relationship, so far as page numbering is concerned, between Exhibit No. 127 and Exhibit No. 125. For example, it will be found on page 4 of this Exhibit No. 127 that the items shown are the identical items shown on page 4 of Exhibit No. 125. That example illustrates generally the relationship between the arrangement in the two exhibits. That is true down to and including page 64 of Exhibit No. 127. The detailed data in Exhibit 125, pages 66 and following, provide the underlying details for weighing out the observations which I made and applying the percent condition factors. Having applied those percent condition factors to those details in pages 66 and following of Exhibit No. 125, I have produced the condition figures shown in summary form in Exhibit No. 127.

I do not mean that I applied the percent condition to all the details of the units shown on pages 66 and following in Exhibit 125, but I did apply it to such details as it was necessary to use, and the detail in Exhibit 125, pages 66 and following through to the end, are the details of the same property shown in my Exhibit No. 127.

In 1938 I began by an inspection of the equipment in the Chicago office; then went to Amarillo and made an inspection first of the equipment of Texoma Natural Gas Company in the field, the gathering system, wells, well measuring stations, and of the Fritch gasoline plant and compressor station, and followed that through on the transmission line of Texoma Natural Gas Company up to its connection with the property of Natural Gas Pipeline Company of America.

The inspection began in the Chicago office on March
957 24 and was completed at Joliet on April 4, 1938. In the 1939 inspection I started at the Amarillo end of the line on May 16, and went across the system in the same fashion, completing the inspection in the Chicago office on May 29. During the 1938 inspection, I was accompanied throughout the trip by Mr. Mark Burlingame, one of the engineers for defendants. In each division we were also accompanied by the division superintendent or the division foreman, or both. In the 1939 inspection, I was accompanied throughout the trip by Mr. Mark Burlingame, and by Mr. Johaningsmeyer, an engineer for the Federal Power Commission. We were also accompanied in the districts by the respective district superintendent or foreman, or both.

Referring to Exhibit No. 127, and in particular to pages 4 to 6, covering Account No. 1000 "Lands in fee", and pages 7 and 8, covering Account No. 1002, "Rights of Way", it will be noted that no depreciation is shown. That is due to the circumstance that these accounts cover fee lands and rights-of-way, respectively and that character of property is not depreciable.

Before starting out on each of the two inspection trips to which I have referred, I instructed the management to cause holes to be dug at approximately 5-mile intervals over the entire pipeline system allocated on the gathering system as between the various sizes generally in proportion to the mileage of the sizes. These holes were opened and were so dug that there would be six feet of pipe exposed, four feet of the exposed pipe was scraped clean of all protective coating. The bitumastic enamel was removed and the wrapper was removed so that four feet of exposed pipe could be inspected. Two feet of protective coating was allowed to remain in place so that an examination of the condition of the coating itself could be made. The holes were so dug that clearance was allowed on both sides, and underneath the pipe, so that the pipe could be examined clear around in circumference, and so that the protective coating could be examined for two feet at the end of the bare four-foot section of pipe. For the 1938 inspection there were 42 holes on the gathering system of Texoma, 15 on Texoma's main line and 168 on the pipeline of Natural Gas Pipeline Company, a total of 225 holes.

In the 1939 inspection, on my instructions holes of identical size and character were opened, except that the holes were spaced at approximately 10-mile intervals and staggered with respect to the holes dug for the 1938 inspection.

(At this point counsel handed the reporter a map entitled "Natural Gas Pipeline Company of America, Texoma Natural Gas Company Bell Holes Dug For Inspection of Pipe—Total System". At the direction of the Examiner, the document was marked Exhibit No. 128 for identification.)

In the 1939 inspection, there were 15 holes dug on Texoma's gathering system, 7 on Texoma's main line, and 83 on the lines of the Natural Gas Pipeline Company of America.

Exhibit No. 128 is a map showing the location of the inspections made of pipelines for the inspections both in 1938 and 1939. At the lefthand end of this map and divided off by vertical lines from the main portion of the map, is an enlarged map section showing the pipelines of Texoma Natural Gas Company. At a point in the southwest portion and near the southwest corner of Hutchinson County may be noted the name "Fritch". This is at a junction of a red horizontal and a red vertical line, and that junction point is at the location of the Fritch Compressor Station and Fritch Gasoline Plant. From that point there ex-
958 tends to the right a red line nearly horizontal running
out into Gray County. I am referring to the heavy red line and not to the smaller, lighter red line. This line represents the gathering system bringing gas from Gray and Carson Counties into the Fritch Gasoline and Fritch Compressor Stations. Running to the left of this same central point and extending out into Moore County is another heavy red line connected up to lighter red lines, which represents the gathering system of Texoma Natural Gas Company, bringing gas from Moore County. In other words, there are two separate gathering systems, one going to Moore County and one going to Gray and Carson Coun-

ties. The smaller red lines are branch lines off of the larger gathering trunk lines, and the smallest ones are connected to wells which are represented by stars.

The numbers in the orange circles represent numbers assigned to inspections made on this gathering system in the 1938 inspection. From the orange circles the blue lines leading down to the red lines lead to the locations on the pipelines at which the respective inspections were made. The green triangles and the lines leading from them up to the red lines indicate the location of inspections on this system made in the 1939 inspections. I may also add an explanation on this section of the map, that from the Fritch Compressor Station and Gasoline Plant running to the northeast there is shown a heavy red line with a multiple crossing of the Canadian River. This is the main transmission line of Texoma Natural Gas Company. And the red line in the right-hand section of the map from Fritch in a generally northeasterly direction to the Nebraska-Iowa line is the main pipeline of Texoma Natural Gas Company and Natural Gas Pipeline Company of America. I might point out that at the point where this pipeline crosses the Missouri River the map has been bent; that is, the line was changed so as to get this map all on one narrow strip, and that the true direction of the line east of the Missouri River would be properly delineated on this map if the map were cut in two at the Missouri River and two sides of the Missouri River brought into conjunction, to show the right angle at which the line turns at the Missouri River Crossing.

I will now take as an example of what I did when I made those inspections in 1938 and 1939, one of the green triangles leading up to either the main gathering lines or the smaller gathering lines of Texoma Natural Gas Company. We will take No. 5X which represents an inspection made in 1939. This inspection was on a 24-inch Gray County gathering line, on what is called the Gray County main line in the gathering system. The line was welded. The coating on this particular section was asphaltic. The amount of covering over the pipe—this is not the depth of the trench but the distance from the normal ground level to the top of the pipe—was 60 inches. The inspection was made at station 1170 plus 74. This station to which I refer is the survey station and is the company's field designation for a particular point in the survey. It is the engineering record of distances along the line. The location was 50 feet north of drip number C-24 W in Section 38, Block 4, I & G N Survey, Carson County, Texas. The soil was loam with caliche streaks. The coating was good, but light surface rust and light etching on top of the pipe could be seen.

By "light etching" I mean the effect of corrosion which could just barely be detected by looking at it, appearing as though it might be etching with the application of acid, or something of that sort, a very light surface attack. There were no pits and I assigned to the pipe the condition of 99 percent, and to the protective coating a condition of 70 percent.

959 We will take 25X. That point is on the line of Natural Gas Pipeline Company of America. The line is 24 inches, is a combination welded and coupled line. The protective coating was bitumastic enamel. The cover over the line was 67 inches. The location was at mile 31, station 5,088 plus 17. "Mile 31" means that it is the 31st consecutive section of land through which the line has passed. It does not mean necessarily the 31st mile. The survey station shows that it is not that. This location is in Section 23, Township 4, North, Range 22, East, Beaver County, Oklahoma. The soil was clay to caliche sand. The coating was poor from flux and soil indented with small rust stains. Light etching on pipe and very small pits. I measured the depth of these pits and found that in the first one-foot section the pit depth was 10 mills. A mill is 10/1000 of an inch. There were 4 feet of bare pipe exposed. This 4 feet was divided into four one-foot sections. Where pits were found, the procedure was to measure the pits on each of those one-foot sections and the depth of the deepest pit was recorded for the particular one-foot section. In measuring the depth of these pits I used a Moorlane pit depth gauge, an instrument designed particularly for measuring the depth of pits in pipe.

I have given a great deal of study to the relationship of the depth of pits and extent of pitting to the condition and usability of pipe. The value of pipe is affected, of course by the depth of pits and by the relation of those depths to wall thickness. It is also affected by the diameter of those pits, and by the relationship of that diameter to the circumference of the pipe. It is also affected by the distribution and frequency of pitting and by the character of the pitting, or the size of the eroded areas, if any. I know of no way to relate all those factors to produce a mathematical expression by which you may determine the condition of pipe. It is a matter of judgment in making the detailed examination as to what the condition of the pipe is. In my case, the condition of the pipe was based upon my many years' experience in that kind of work. Without that experience in such work my opinion would not be worth anything on the value of pipe that has been in service.

From my observations in the State of Oklahoma on the property of Natural Gas Pipeline Company of America I determined a condition for the pipe which applies to the fittings and the installation of 98 percent, for the protective coating 62½ per cent, for the river crossings and line walkers bridges 90 percent, and for sleeve houses and pipe racks 95 percent. Those conditions, applied to the reproduction cost new values determined by Mr. Hamilton, produce a present value figure of $1,215,481, which is 94.07 percent of the reproduction cost new figure of $1,292,094.

(Objection by counsel for the two Commissions to the qualifications of the witness to testify as to present value overruled.)

On pages 8 and 54 of Exhibit 127, in Account No. 1005, "Main Lines," for the two companies, I divided the line into States: Texas, Oklahoma, Kansas, Nebraska, and so forth. That was done because I thought a more balanced weighing out of the observations could be obtained by taking the states as units for grouping the observations and applying the results to the reproduction costs figures, than by simply averaging out the figures and applying them to the property as a whole. It was convenient to do that because the valuation itself had the property grouped by states.

960 In determining the condition percent of the main lines, I took into consideration the findings made from the examination of the pipeline at the various points shown on Exhibit 128. Going back to my examination of the hole at No. 25 X, shown on Exhibit 128, I may add that I found the pits on the four one-foot sections to arrange in depth as follows: Ten mills, ten mills, six mills and ten mills. I assigned to the pipe a condition of 97 percent and to the protecting coating a condition of 30 percent.

In my examination of the pipeline of both of these companies in 1938 and 1939, I made observations as to the depth of cover over the top of the pipe in each of the states. On the Texoma Natural Gas Company property, the average cover determined from my observations is as follows: On the 24-inch main line, 52 inches; on the 24-inch gathering line, 51 inches; on the 16-inch gathering line, 60 inches; on the 10-inch gathering line, 44 inches; on the 8-inch gathering line, 34 inches; on the 6-inch gathering line, 27 inches; on the 4-inch gathering line, 30 inches. On the 24-inch main line of Natural Gas Pipeline Company of America, I found the average cover in the State of Oklahoma, 56 inches; in Kansas, 56 inches; in Nebraska, 57 inches; in Iowa, 62 inches; and in Illinois, 63 inches. The over-all average is 59.6 inches. On lines other than 24-inch, such as lateral and river approach lines of sizes other than 24-inch main lines, I found the cover in the State of Nebraska to be 57 inches; in Iowa, 44 inches; and in Illinois, 47 inches.

The meter station mentioned on page 8 of Exhibit 27, under Kansas, is the tie-over connection between the systems of Natural Gas Pipeline Company of America and Panhandle Eastern Pipeline Company. Most of the equipment at that station is above ground and visible, and can be readily seen. I looked it over and made notations as to its condition. The property actually showed no deterioration except the quality of the paint materials on there. The allowance there is to take care of deterioration that would not be visible. Shown on page 8 are a meter station and a regulator station in Illinois. The condition of these stations is shown at 97 percent. Those are the stations at Joliet, Illinois. I examined those two plants in detail and made notations on location as to the condition of the property at those plants.

As shown on page 8, I found the average condition of the main lines of Natural Gas Pipeline Company to be 95.66 percent. In the second column, the reproduction cost new, as determined by Mr. Hamilton, was $26,558,660. Applying my percentage of depreciation, the deduction was $1,152,908, leaving a reproduction cost new, less depreciation, designated under the column "Present Value," of $25,405,752. The same explanation is true as to Account No. 1005 of Texoma shown on page 54 of the same exhibit. The items were arrived at in the same fashion.

The meter station, designated under the word "Oklahoma" on page 54, is the State line measuring station at the point where the gas delivered by Texoma Natural Gas Company to Natural Gas Pipeline Company of America is measured.

Turning to pages 9 to 23, inclusive, which show Account No. 1006, "Compressor Stations of Natural Gas Pipeline

Company of America" and to pages 55 and 56, which 961 show Account No. 1006, "Compressor Station of Texoma Natural Gas Company," I made an examination and inspection of all these compressor stations. In general, I first went into the office of each individual compressor stations. I noted the condition of the office furniture and equipment, made notations on specific items. I would then proceed to the auxiliary building, the building which houses the electric power generating equipment and the water pumping equipment, and the machine shop, the electric lighting equipment, storage battery equipment.

Station No. 2, sometimes referred to as the Perryton Compressor Station and sometimes as the Gray Compressor Station, is the second station on the system, Fritch being No. 1. The facts as to this station are set out beginning on page 9. The first line under Compressor Station No. 2 is Auxiliary Building, on which I found the condition percent to be 92.98. That percent condition is the composite result of the application of the observed condition to the reproduction cost estimate of various components of the building. As a result of my inspection of this building, I have assigned to the superstructure a condition of 95 percent; to the foundations, a condition of 95 percent; to the floors a condition of 90 percent; to the curbs a condition of 95 percent; to the stairways a condition of 95 percent; to the down-spouts and gutters, a condition of 95 percent; to sumps, a condition of 95 percent; to pipe trenches, a condition of 95 percent; to lighting, to heating, and to plumbing, a condition of 90 percent; to partitions, a condition of 95 percent. Applying those conditions to the reproduction cost figures for the specific items mentioned, I obtained a present value of $11,281, which is 92.98 percent of the reproduction cost new of $12,144. This is the same thing as a deduction for depreciation of $853.

Cross-Examination Interposed by Mr. Slaff.

I didn't assign percentages to every individual item making up the equipment classification under the terms of lighting or heating. I assigned to lighting separately a condition of 90 percent. I grouped the heating and applied to the heating group 90 percent. I grouped the plumbing, and applied to the plumbing a condition of 90 percent. I grouped the partitions and applied to them a condition of 95 percent. There are some instances, in the case of large structures, where I made specific notations further breaking down information as to superstructures, but generally the example I have given applies to the major structures. Now for small structures I did not weigh out the values in that fashion, but assigned to the individual structure an over-all condition based upon the observations. (Objections by counsel for the two Commissions to the designation of "reproduction cost new less depreciation" as "present value" overruled.)

Direct Examination Resumed by Mr. Hedrick.

Column 1 in Exhibit 127 is my work. Column 2 in this exhibit is as shown, the reproduction cost new to which Mr. Hamilton and his associates have testified in this case in connection with the presentation of Exhibit No. 125. The amount of the depreciation deducted as shown in the third column is my determination, and that determination is made by applying to reproduction cost new values, of which Mr. Hamilton's Exhibit 125, the condition which I determined by my investigations. The application of those conditions to the reproduction cost new figures produced the figures in the right-hand or fourth column under the
heading "Present Value." Throughout the entire ex-
962 hibit, the last three columns are the same as are shown
on pages bearing the same numbers in Exhibit 125,
with the exception of the title pages and the index pages. (Motion by counsel for the two Commissioners to strike testimony with respect to present value denied.)

After I made my examination of the auxiliary building referred to on page 9, my general procedure was to proceed from the auxiliary building to the main building. The main building is the largest structure at these stations, and it houses the gas engine driven compressors, that constitute the main equipment of the plants. At this building I have inspected the condition of the superstructure, the engines and their attached compressors, and the condition of the floors, the lighting systems, of the ventilating systems, if there were such; and made notations as to the condition of the various items of equipment in that structure. Then I would generally proceed to look over the cooling tower and the yard piping of the station, and generally from there to the warehouse. Most of these stations have located on the premises a warehouse for the use of the pipeline operations and maintenance crews. I would then inspect that structure and the equipment that was housed in it. Then I would generally proceed to inspect the condition of the dwelling houses, the cottages, the boarding house, and so forth, and would during the course of my examination make an inspection of the sidewalks and roads and fences and the shrubbery and lawns. I went through that general procedure at each station of the Natural Gas Pipeline Company of America and at the Fritch Station of Texoma Natural Gas Company.

At the compressor stations I made separate notations as to the individual structures and separate notations as to the condition of each of the major items of equipment. There were some minor items of equipment, of course, at each plant, on which I did not make individual notations. Little things like that in the final analysis have practically no effect upon the determination of values.

The percent condition shown in column 1 on pages 9 to 23, for Natural Gas Pipeline Company of America, and 55 and 56, for Texoma Natural Gas Company, represents my judgment of the condition percent of those various items listed. I would like to explain with reference to that volumn of conditions that the items of condition which are even percents are in general individual observations of the particular item, while those which are fractional percentages are the result of weighing out a number of observations against the reproduction cost new figures given in detail in Mr. Hamilton's Exhibit No. 125. That is not always the case, but that is the general rule as to the conditions. Where I had a composite figure such as for the main building on page 9, of 94.83 percent, and in other places where it shows odd percentage, I arrived at that composite percent in the same general manner as I testified in connection with the auxiliary building, which is shown in the first line on that page. In general, the ones where it shows an even percent are separate items where there was no composite involved. That applies all the way through Exhibit 127.

Passing to page 24, which shows Account No. 1008, the telephone system of the defendant Pipeline Company and on page 60, which shows the same account, representing the telephone system of Texoma, the term "pole lines" means the outdoor line equipment consisting of poles, guy wires, anchors, cross-arms, braces, brackets, insulators, wires, tie wires, in general the telephone lines running cross country,

as distinguished from the ringing and connecting equip-
963 ment and phones at specific locations such as compres-
sor stations and warehouses. Equipment of the kind last mentioned is designated by the term "stations" as distinguished from "pole lines."

At each one of the stations, compressor stations, and at each one of the warehouses where the equipment was located, I saw the equipment and I made notations as to its general condition. In going over the pipelines of the two companies, I had opportunity at very frequent intervals to see the pole lines, because those pole lines in general are fairly close to the pipelines. On the property of the Texoma Natural Gas Company in the Amarillo field, the telephone lines in general are along the pipe-line right-of-way, but on the system of the Natural Gas Pipeline Company of America, the telephone lines are in general along the roadways, and they may be seen and inspected in driving from one of these test hole locations to another at numerous places. So that I had an opportunity to observe the condition of telephone line equipment just about as frequently as I observed the condition of pipelines.

Mr. Johningsmeyer was generally, but not always, in a separate car during these inspections, and whether the pole line was identified to him throughout the distance there, I could not say. I know it was in some instances, but in how many I don't know.

Cross-Examination Interposed by Mr. Slaff.

In some instances, I stopped and made individual notations of individual poles and in other instances I just looked at them as I drove along. My working papers will not disclose what I did in any specific instance. They will merely disclose that I made an observation. They will show an observed condition as applied to pole lines for each location at which I made an observation. They will not show whether that observation was one which I made in transit or one which I made standing still. My work sheets will show that this observation at or near a certain pipeline survey station number, or between certain pipeline survey station numbers was made. It will show only that at some point between those two locations I inspected the telephone lines. It will not give the pole number. It will include a percent condition for the location at which I saw the pole line. My working papers will not include the percentage condition for the entire pole line between the two locations indicated on them. I saw the pole line at a specific point and the extent of that specific point may have been a couple of poles or it may have been a mile or two if I rode along. My records will not disclose. They will show that I observed that line and made a notation as to its condition. If I drove from bell hole No. 125 to hole 126 and saw the telephone line in between there, I would make a notation as to the condition of that line as I saw it between those two pipeline inspection locations. That is an over-all percentage for that two miles, or five miles, or whatever it may be. In a number of cases my observations were made as I drove along without stopping.

Direct Examination Resumed by Mr. Hedrick.

I also stopped at a great number of telephone poles and made detailed inspection of them. Whenever I saw anything of some unusual character, I stopped and made an inspection. I examined the butts of poles in a number of cases minutely to see what shape the creosoting was in and how much protection still remained.

Cross-Examination Interposed by Mr. Slaff:

964 I put down my observation as to the over-all condition which I judged that line to be in, but I did not make specific notations in my work sheets to the effect that I had stopped at a specific pole and observed conditions of the pole, of the creosoting, of the butts, the cross-arms and other specific notations.

Direct Examination Resumed by Mr. Hedrick.

In addition to actual viewing or inspecting the property myself, I took into consideration other matters in arriving at the percent condition. At each station I made an examination of the operating, maintenance and repair records. These records disclose the micrometer measurements of the various engine parts made to the annual overhaul periods and disclosed repairs made to various portions of the equipment. I examined those records and took those records into consideration in fixing the condition of the equipment at the compressor stations.

Turning to pages 25 to 29, inclusive, and page 61 of Exhibit 127, which refer to Account No. 1009 "Meters and Regulators", I visited each of the stations listed and inspected the equipment in service at those stations. As to the reserve equipment, I have not seen all of those items, but the equipment itself I have seen, and the condition assigned to the equipment in reserve is based upon the condition in which I found the equipment in service. The term "in reserve", as used here, means exchange equipment held for the purpose of changing the equipment when repairs and adjustments are required. I find almost invariably the condition percent of the meters and regulators in service is more than that in reserve, because for the equipment in reserve I have allowed for the known fact that some of it is in reserve for repair and adjustment. Consequently, those that are not in service on account of repair and adjustment, the percent condition would be lower than those in service.

Cross-Examination Interposed by Mr. Slaff.

Where the percentages are the same for equipment in service as in reserve, that merely means that I did not make the extra allowancs on that particular equipment. It simply means that I did not make an additional allowance on that equipment of adjustment. It is not necessarily true that all this equipment is out for adjustment and repair. That is true in some cases. In most cases I make such an allowance simply to allow for the possibility or necessity of repairs and adjustment on equipment that was out of service. Where I did not make the allowance it was simply because the equipment was out.

Direct Examination Resumed by Mr. Hedrick.

As I have stated, I saw all of the equipment that was in service. On that I have allowed 95 percent and the percentages which are shown in the first column. Where the equipment was in reserve on account of repairs, I generally made an allowance for the fact that it was in reserve because repairs and adjustments were in process or contemplated or probably necessary. I have not made a determination with respect to each of those items of reserve equipment, as to whether repairs were then necessary or not, but I have in general made an allowance for equipment in reserve because, in general, the equipment in reserve is out for the reason that once in a while this equipment has got to be repaired and adjusted, and some of this equipment which is in reserve is in the process of repair and adjustment.

965 I have been at the location of the structures shown for Account 1010 and shown at pages 30 to 34 and 62 and 63 of my Exhibit 127. I made notations as to the condition in which I found those structures. Many of them are meter and regulator station buildings. Some as on page 32 at the top are for other purposes. This Red Oak warehouse is a group of structures, one housing materials and equipment for the pipeline forces for repair and maintenance and the other housing equipment for the compressor station repair and maintenance work. I inspected those structures and assigned to each structure a condition based upon those observations. With respect to the structures in Account 1010 for Texoma shown on page 62 and continuing on page 63, the first item is "Meter Stations, Amarillo Field". I inspected a large number of such meter stations, both in 1938 and 1939, and determined their average condition was 95 percent. The other structures shown, the Dumas and Kingsmill warehouses, and the meter station on the main line in Oklahoma, I inspected and made notations at the site as to the condition of the items shown, except that there may be some minor items on which I did not make notations at the location.

Cross-Examination Interposed by Mr. Slaff.

With respect to meter stations of Texoma shown on page 62 as being in 95 percent condition, I examined many of the meter stations in the field and arrived at a 95 percent condition and applied that to all the meter stations in the account. My work sheets show percentages for each individual meter station that I examined. I went out and looked at the first meter station which would be shown on page 862 of Exhibit 125 and having examined it I put down a certain percent for the condition of that meter station, if I saw that particular station. Then I went to the next one and looked at it and put down another percentage, whatever it was, for that one, and so on as to all those stations that I examined.

I added up the percentages and then used the over-all figure of 95 as a round figure to represent the condition of all meter station structures in the Amarillo field. The figure that I actually came to, instead of the figure I used, was 95.2 percent. I applied 95 percent to the figure of $27,090 and arrived at the present value figure of $25,736, as shown on page 62 of Exhibit No. 127. That results in a figure of $1,354 for depreciation to be deducted, and that figure of $1,354 for depreciation to be deducted is the figure for that item of property which I furnished to Mr. Hamilton for his use. The 95.2 percent condition to which I referred a moment ago is a numerical average of my observations on meter station structures which I observed. We will assume that for the first meter station which I examined, I arrived at 90 percent condition, for the next one 97 percent, the next one 93 percent, the next one 92 percent and so on. When I was all through I added up all those percentages and divided the total by the number of meter stations I had examined.

Direct Examination Resumed by Mr. Hedrick.

The 95 percent is the average for all that I examined, I then took that average percentage and applied it to the reproduction cost new of the total. If I had applied the percentage that I found for each of the items in question to the cost of each item as determined by Mr. Hamilton and got a present value figure for each and then added all such figures together it would be exactly the same if each structure cost the same amount. I am not exactly certain that each structure did cost the same amount. This is true since from Exhibit 125, pages 862, 863 and 864, it is apparent that with some minor exceptions all these structures cost the same amount. They were so nearly
966 alike that the cost should be the same except in a few instances where the building might vary slightly from standard.

Turning now to pages 35 and 36, which show Account No. 1011, "Branch Lines to Distributors"; we will take the first one there in Barton County, a lateral, where the condition percent is 95. That refers to a branch pipeline through which deliveries are made to consumers of gas off of the main pipeline system. The percent condition which I have assigned to lateral lines is, in general, based upon the condition found by examination of the main line itself. In the State of Kansas, as may be noted on page 8 of Exhibit 127, I found that the main line was in 95.72 percent condition. I therefore assigned to the lateral line listed as the Barton County lateral a condition of 95 percent. That Glasco lateral, also in Kansas, was constructed, as I recall it, at a considerably later date than the main line itself. That is my present recollection of that. Considering the condition of the lines, that is of the main line found in this area, I have assigned to the Glasco lateral a condition of 97 percent. It is my judgment that the figure of 95 that I used for the Barton County lateral is justified from my knowledge of the conditions existing on the main line. And it is my judgment that the percent condition of the Barton County lateral is not less than 95 percent. I saw the equipment in Barton County, which constitutes the second item. It consists of some direct meters. There is no deterioration visible from an exterior inspection, except as to the condition of paint on that equipment. I have made an allowance, however, for wear and tear that would not be disclosed upon exterior inspection.

I made the same type of examination of the regulator station, shown under the caption "Glasco", as being in 95 percent condition, as I made of the meter and regulator station in Barton County. That is true as to all of the meter and regulator stations shown on pages 35 and 36.

At the various locations where the tools of Natural Gas Pipeline Company and Texoma, as listed at pages 37 and 63, under Account No. 1013, in Exhibit 127, are kept, at the compressor stations, pipeline warehouses and field warehouses, I have inspected tools and equipment. This consists of the equipment used by the pipeline and compressor station crews for maintenance and repair work. Included in this classification are portable electric lighting units, welding equipment, excavating equipment, and in general the full line of equipment required for pipeline or compressor repair and maintenance. I arrived at the percent condition of these tools and appliances from a price listing of this equipment compiled by Mr. Hamilton's organization. To a price listing of this equipment, I have applied my observations as to the condition of the equipment and have arrived, by that process, at the weighted values of condition in percent as shown on pages 37 and 63 for these classifications.

Cross-Examination Interposed by Mr. Slaff.

I had a listing of these tools and equipment. For the major items, I had specific observations as to their condition. This equipment was priced by Mr. Hamilton's organization at its reproduction cost new. I applied specific observations to those specific items of major equipment. The small hand tools I lumped together.

967 *Direct Examination Resumed by Mr. Hedrick.*

Included within the classification of tools and appliances in this particular item are wrenches, tongs, excavating equipment, welding equipment, and water pumps.

Cross-Examination Interposed by Mr. Slaff.

To the small tools I applied the percentage independently, based upon the general observation as to the condition of small tools. For the major items of equipment I applied specific observations. Those are all weighted out, and from the weighting out I arrived at the overall condition of each group. I applied the same procedure to each one of those three groups of tools. I have, as the result, a different percent condition for each of the three groups.

On page 542 of Exhibit No. 125 are listed tools and appliances in the State of Kansas at three locations. Bloom compressor station, Glasco compressor station, and Heizer compressor station. Of the amount at the Bloom compressor station of $6,483, $2,418 represents equipment, acquired in 1938 and 1939, consisting largely of caterpillar tractors, water pumps, portable electric lighting plants, and similar equipment. To that equipment I have applied an over-all figure of 97 percent, resulting in a deduction of $73 from reproduction cost new. To the balance of the reproduction cost new of that equipment I have applied 75 percent against $4,065, resulting in a deduction for depreciation of $1,016. This is a total deduction for depreciation against that equipment of $1,089. Now to develop the 75 percent figure, I will have to get back further into other detail sheets. For Glasco station in similar fashion, of the total amount shown on page 542 of Exhibit 125 of $7,042, $2,967 was recently acquired equipment, to which I have assigned a condition of 97 per cent, resulting a deduction of $89. To the balance of $4,075 I applied a condition of 80 percent, resulting in a deduction of $815. For Heizer station, of the total amount shown on page 542 of Exhibit 125, of $13,053, $6,615 was recently acquired equipment, to which I have assigned a condition of 97 percent, resulting in a deduction for depreciation of $198. The balance of the equipment in the amount of $6,438 reproduction cost new has been assigned a condition of 70 percent, resulting in a deduction of $1,931. The total of those deductions for depreciation of tools and appliances in Account 1013 in the State of Kansas is $4,122.

Direct Examination Resumed by Mr. Hedrick.

Referring to pages 37 and 63, showing Account 1014, "General Laboratory Equipment of Natural Gas Pipeline Company of America, and Texoma Natural Gas Company", this equipment includes equipment at the Joliet, Illinois meter station and regular station used for the testing of natural gas and for testing and calibration of measuring instruments. It consists of thermometers, gauges, calorimeters, chemical balances, specific gravity apparatus, gas analysis apparatus, and, in general, equipment of that nature.

I inspected the equipment at location and made specific notes as to the condition of the major items and have weighed those observations out against the prices to Mr.
Hamilton's figures of reproduction cost. I did this
968 generally in the same way as I did in the case of other
miscellaneous equipment concerning which I testified. I arrived at the figure of 93 percent as a result of that weighting out.

It was a mathematical process of multiplying values by observed conditions. This 93 percent results from the application, for example, to the "apparatus for determination of deviation from Boyle's law" of a figure of observed condition. I applied that condition to the value of the equipment, as fixed by Mr. Hamilton in his sheet for reproduction cost.

Taking other items of equipment in the same fashion, I applied to the values shown in the reproduction cost estimate the figures of condition which I observed, and added both columns, reproduction cost figures and the resultant figures derived by the application of the percent figures, and the ratio of those two sums produces the weighted condition, which in this case would be 93 plus or minus. I have rounded it out at 93 percent. (Motion to strike witness' answer by counsel for Illinois Commerce Commission denied.)

The general laboratory equipment of Texoma, shown at page 63, Account 1014, is of the same character in part as the equipment in the laboratory at Joliet. In addition it contains equipment for the testing of petroleum products. This latter equipment is locted at the gasoline plant at Fritch. I arrived at the percent condition of 90 shown on page 63 just as I arrived at the percent condition of equipment shown on page 37.

Account No. 1015, "Automotive and Transportation Equipment," includes automobiles, trucks, tractors, and trailers. The percent condition assigned to this equipment was arrived at from a consideration of the mileage which the various pieces of equipment had recorded up to June 1, 1939. I gave consideration to the fact that cars used by Texoma were largely used in the Panhandle field, where roads were poor, or non-existent, and where the effect of mileage upon the condition of that class of equipment is greater than is the same amount of mileage upon cars used further north on this system where roads are better. There is not nearly so much dust on the north end of the line as on the the south end. The dust condition tapers down to almost nothing as you proceed northward. I took that factor into consideration in arriving at the percent condition of this equipment. In arriving at the percent condition of automobiles, I estimated that an automobile in the field system of Texoma which had traveled 25,000 miles to be depreciated approximately one-third. An automobile with the same mileage on the system of Natural Gas Pipeline Company of America, I estimated had depreciated approximately 25 percent. The company records were available to me so that I could determine the mileage on this transportation and automobile equipment. I have seen trucks that had more than 50,000 miles on them, and I think I have some observations on cars that have exceeded that.

Cross-Examination Interposed by Mr. Slaff.

969 If I had a car which showed exactly 25,000 miles of mileage I would give it a percent condition of 66.66. In applying the conditions I took into consideration the mileage on the basis I have explained but have used them all as event percentages without fractions. If it was 12,500 miles, I used half of 33⅓ percent or 16⅔ percent. The basis upon which I arrived at the relationship between mileage and percent condition was that in general the cars on the Texoma system can be exchanged on the basis of a full life rating of 75,000 miles, and on the Natural Gas Pipeline Company of America system they can be exchanged on the basis of a full life of 100,000 miles. That is, if they had about 50,000 miles they can be turned in at approximately 50 percent of cost.

Direct Examination Resumed by Mr. Hedricks

Account No. 1016 for Natural Gas Pipeline Company consists of the office furniture and fixtures, calculating machines, typewriters, and so forth, at the compressor stations and at the warehouses on the pipeline sysiem. In the State of Illinois, the same class of equipment is found at the Joliet meter and regulator station and in the Chicago office. I arrived at the percent condition of that office equipment, furniture and fixtures, by weighing my observations against the reproduction cost new of Mr. Hamilton in the same manner I have described for other equipment where different classes of equipment were carried under the same Account number. The resultant figures have been rounded off to even percentages. In the case of Texoma that equipment shown of page 64 consists of the furniture and fixtures at the Fritch gasoline plant, Fritch compressor station, the Dumas warehouse, Kingsmill warehouse, and at the operating office of the company in Amarillo. I inspected the equipment in each one of these locations, in each office, and upon my first inspection when I did not have available any inventory. I listed the equipment as I inspected it. Upon the second inspection, I had that listing available and went over it again. Now I have seen, I think, every bit of this equipment; except a few minor and unimportant items that I may have overlooked in going through the various offices.

I did not see all of the wells of Texoma Natural Gas Company. I really do not know how many I saw. I made specific notations as to 41 but I saw a great many other wells on which I did not make specific notations. There were probably 25 of these additional wells. I actually saw all of the wells on which I made notations. The company records as to all of these wells were made available to me. These records show the equipment in the well, its age and the work that has been done upon it. So far as an examination of these wells is concerned, very little deterioration is disclosed. Of course, in an examination of the well from the surface, only the top fittings are visible. If a well is in very bad shape that can sometimes be detected by leakage showing up at the surface. Nothing of that sort was visible in connection with any wells which I saw. I have determined the amount to be deducted for depreciation for these wells on the basis of age of wells.

To wells drilled in 1938 and 1939 I have assigned a condition of 100 percent. To wells drilled in 1936 and 1937 I have assigned the condition of 98 percent. To wells in 1934 and 1935, I have assigned the condition of 96 percent. To wells drilled in the years 1930 to 1933, inclusive, I have assigned the condition of 95 percent. To wells drilled prior to 1930, I have assigned the condition of 92½ percent, 970 with the exception of a few very old wells drilled about 1926 and 1927, to which I have assigned a somewhat lower percent condition, and with the exception of a group of wells in Gray and Carson Counties connected to lines other than those of Texoma Natural Gas Company to which I have assigned the condition of 50 percent. This latter assignment is based upon information which has been made available to me as to the condition of those wells below ground. There are four of those wells: G. H. Saunders, Nos. 6, 10, 12, and 13, which fall under this 50 percent classification. There are others, the M. A. Shaw well, and another is the McLarty-Lester "B" well No. 3. Based on my experience and the information which I obtained concerning these wells, it is my judgment that the percent condition of each of these wells is as is set out on pages 41 to 54 of my exhibit.

Account No. 1007, beginning on page 57, shows the equipment in the gasoline plant at Fritch. I have made two inspections of this gasoline plant, the equipment of which is listed in Exhibit 127 under Account 1007. Upon each of these inspections I have noted the condition of the various items of equipment and have applied those observations against the cost of reproduction new provided by Mr. Hamilton. In the case of major structures, such as, for example, the boiler house on page 57, the figure of percent condition of 94.31 is a weighted figure, arrived at by multiplying my observations to component parts of this structure to arrive at the overall condition. The majority, however, of the figures in this column of condition percent under this classification are direct observations of the overall condition of the items to which they are applied. I have applied separate observations as to conditions to the following divisions of the reproduction cost estimate of Mr. Hamilton for this structure: The superstructure, the foundations, the floors, the stairways, down-spouts and gutters, lighting, plumbing, partitions, ventilators. Those divisions of that building will be found in Exhibit 125 on pages 797 and 798.

Account 1012 shows a list of the drilling and clean-out tools of Texoma. I saw some of this equipment at the Dumas warehouse and some at Kingsmill warehouse. I saw some of it in use upon a well. My observation of this equipment indicates that it had lost about 30 percent of its value, so I assigned to it a condition of 70 percent overall. I did not go into any specific detail as to individual items of tools. I simply assigned an overall condition to this group of equipment.

At page 64, Account No. 1024, appears a list of the booster station equipment of Texoma. That is the small 40 horsepower unit about which other witnesses have testified. It was practically new and just broken in on June 1, 1939, and I assigned to it and the miscellaneous equipment, piping, and the building at that station, a 100 percent condition.

From my experience in the natural gas business, and in conducting investigations to determine the condition of natural gas properties about which I have testified, and from my inspection of these properties and from the original records and information with which I have been supplied, it is my judgment that the percent condition for each of the items listed in Exhibit 127 is as set out opposite each one of these items. And it is my judgment that the depreciation which should be deducted from reproduction cost new, is

the amount set out opposite each one of those items
971 and shown in the third column in Exhibit No. 127. I
furnished the figures shown in the third column of Exhibit 127 to Mr. F. C. Hamilton and men working under him for the preparation of Exhibit 125, and they have used those figures in the last two-named exhibits.

Cross-Examination Interposed by Mr. Slaff.

I have checked each figure in Exhibit 125, on each one of the pages in which my figures, developed and shown in Exhibit 127, are used. The figures under the column "Depreciation Deducted" in Exhibit 127 were furnished to Mr. Hamilton and his organization and were used by them in their Exhibit 125. I have verified that they so used them by checking them myself or having my organization check them.

Direct Examination Resumed by Mr. Hedrick.

I may say that with respect to lands and rights-of-way, there being no deductions, I furnished them the zero figures which Mr. Hamilton used for that zero deduction.

My examination showed that the program of maintenance and operation of this natuarl gas system had kept it in a better state of preservation, in a better of state of maintenance, than any other system with which I ever had any experience. The facilities for accomplishing this have been so carefully thought out and provided for in advance, and the standards have been set so high, that the results are very unusual in comparison with what you find even in the best of other pipeline systems of which I have knowledge, and I am familiar with most of the major gas pipeline systems of this country.

(At this point Exhibit No. 128, the map showing the location of the holes at which the pipeline was inspected, was offered in evidence and received without objection.)

I have checked that exhibit against the actual facts. It was prepared at my direction, has been approved, and it bears my signature in the lower right hand corner of the map.

Cross-Examination by Mr. Booth.

My work has had to do with determining the amount which should be deducted from the reproduction cost new on account of the existing depreciation which I found in the property, shown in my Exhibit 127. This exhibit does not embrace all of the property of these two companies. It does not show the leaseholds and it does not show the undistributed or general construction costs. I made a study of what purported to be the original cost of the companies' property. I made no investigation of their records however to determine the original cost. I had nothing to do with the preparation of Exhibit 125 other than to submit to Mr. Hamilton and his associates the amounts which I determined to represent the existing depreciation, as I have already testified. I had nothing whatever to do with the determination of the reproduction cost new of these companies' properties.

972 Mr. Hamilton and his associates had nothing to do with the preparation of Exhibit 127 other than to supply me with the figures of reproduction cost from his Exhibit 125, with the exception that some of Mr. Hamilton's employees did perform some of the mechanical operations of multiplication, addition and division for me. (Motion to strike witness' testimony and portions of Exhibit 127 by counsel for the two Commissions denied.)

EXHIBIT NO. 127 was offered and received in evidence over objections of counsel for each of the two Commissions, to whom the Examiner granted exceptions. (Objection to Exhibit 125 by counsel for the two Commissions overruled.)

SEPTEMBER 6, 1939

(Exhibit No. 126 for indentification, withdrawn by counsel for defendants.

EXHIBIT NO. 124 for indentification, received in evidence without objection.

EXHIBIT NO. 125 for identification, except the two items captioned "Lands in Fee" and "Rights of Way," offered and received in evidence over objections of counsel for each of the two Commissions, to whom the Examiner granted exceptions. The ruling as to the two above-mentioned items of the exhibit was reserved pending further testimony.)

P.V. 167 46925 S.C.

973 FLOYD C. BROWN, recalled by defendants, testified as follows:

Direct Examination by Mr. Morgan.

(September 6, 1939.)

I am Vice President and General Manager of defendants and have testified heretofore in this case. In the month of May, 1930, I was made Vice President and General Manager of Continental Construction Corporation, predecessor of defendants and was placed in general charge of the construction of the pipeline. I continued in that position through the construction period and have held the same position throughout the period of defendants' operations.

The first major problem confronting me, before any of the design, engineering, or even the office work could be undertaken, was the necessity of assembling an organization. The office staff had to be supplemented by construction engineers and field forces to supervise the construction work. In going about the assembling of the organization, I was offered the privilege by the participating companies of going into their engineering and operating forces and selecting therefrom, either on a temporary or permanent basis, such of their men as I felt would be qualified to undertake positions of responsibility with the new company.

I did not have an intimate knowledge and acquaintanceship of the men, their training or their experience, who were associated with the other participating companies that I had of the men with whom I had been associated in the Empire and Cities Service Companies, so I naturally turned to the latter group of people with whom I had been associated, for the selection of executives, sub-executives and other men who were to occupy positions of responsibility with this new company. I had been with the Empire Companies for approximately 13 years and had what I feel was an important part in the building of that organization during that period of time. A number of the important men in that organization were brought to that company through my efforts; and I had had considerable to do with the training and development of those men, having that intimate knowledge of their technical training and their experience and knowing the degree of responsibility that could be placed upon them. I had the advantage of being able to hand-pick men who were capable of undertaking, with a minimum of supervision, important responsibilities to be imposed by this new project.

You have asked me a question which, as I understand it, divides itself into two parts, first, as to how I went about selecting men, and, second, the purpose I had in mind in selecting and building up the organization. In response to the latter question, I would say that of course it was of primary importance that we select the men who had the greatest experience and training, qualifying them to undertake the responsibilities in connection with the design and selection of material, testing the material and assembling of material for the construction and inspection of the line. We were employing new engineering principles so we had to draw upon that talent which would give us the greatest degree of security in the selection of men, having in mind the objectives toward which we were aiming. We also had in mind in the selection of these men, the need for picking men who were not only qualified to undertake the engineering and construction responsibilities, but also men who would be fitted by training, experience and temperament to undertake or take over the operating responsibilities when the line was finished.

974 We knew from experience of other lines that the men who construct the line, who are familiar with every valve fitting, every foot of pipe, and with the peculiarities encountered in construction, are the men who are best qualified to operate these facilities when the construction work is completed. So, we had an eye looking toward the selection of men qualified not only as construction engineers but as operators, in order that we might pass through that transition state from construction, completion of construction, to the operation of tuning up the line and putting it into operating service.

There is difficulty involved in the selection from the whole engineering profession of the right men to do the particular jobs in connection with the construction and operation of a pipeline system such as this. It is hard to explain without going into minute detail why any good construction engineer might not be thoroughly capable without prior experience of building a satisfactory pipeline. That, however is not true. Good engineers are not difficult to find and it is not difficult to employ good engineers. It is hard however to find good construction engineers experienced in the technique of properly designing and laying pipelines; and that difficulty increases as the diameter of the pipeline increases, and as you commence to inject new and untried theories into the design of a transmission facility such as we undertook in this pipeline.

In assembling our organization, we tried to take into account all those elements and factors and to meet the needs of our company by the selection of the right man and assigning him to the proper position.

The plan we followed worked out surprisingly well. As we neared completion of the construction work in the fall of 1931, we started dividing the responsibility of our supervisory and executive staff in both the field and the office. The change-over did not come about over night. It wasn't anything that took place suddenly or that was not contemplated. We had very definitely in mind how the operating organization should shape up; and we started transferring the responsibility of the men gradually from construction to operation as we neared completion of the line and progressively we started moving gas through the line; first for a purging, and then for a testing of the line itself. As the gas moved progressively up the line, we had it available for testing the engines and tuning them up, putting them on performance tests so that these men who had done the assembling of the machinery and who were familiar with every nut and bolt that went into the assembly were the men then who were best qualified to undertake the tests and finally take over the operations.

They passed through that period there of tuning up not only the machinery but the line itself, taking care of leaks, settling of the backfill and rocking the river crossings. Gas finally was moved into Chicago for a sort of tuning up on a temporary basis of the Chicago District Pipeline Company's equipment. In the beginning, we only put one station in operation until we could start building up the load putting on more stations and engines, so that these men had an opportunity gradually to work from construction over into operation. Now it was about the middle of 1932 before we had fully completed all construction; but we arbitrarily set as the date for terminating the construction as a matter of accounting, the calendar date of January 1, 1932 and fixed that date as marking the termination of construction and the starting of operations, although many of the
975 men and a good part of the organization continued to give decreasing percentages of their time to construction and increasing percentages of their time to operation

until the construction was finally completed. We did not have to go on the outside to bring in operating men to man the organization. We passed from the construction organization into an operating organization with all the knowledge and familiarity that the organization had acquired during the construction period, just as we had planned to do.

I do not mean to convey the impression that I myself selected every man for the construction organization. Obviously, that would not be good organization as I view it and I doubt that my knowledge of the type of men best qualified for many of the routine field jobs would be as good as that of some other men who had more intimate contact in The Empire organization with men of that type.

So what I attempted to do was to concern myself primarily with the selection of the executives, the sub-executives and the staff who were to be engaged in supervisory work. I did not however cease to have an interest in these other men, but having satisfied myself with the selection of the staff men, I then attempted to outline to them what I felt to be my responsibility and the company's objectives and policies and tried to instill in them a sense of responsibility that I expected to repose in them. That is, I wanted them in turn to accept the responsibility of selecting the men who were to work under them to whom they expected to assign other responsibilities and that was progressively carried clear on through the organization.

As an example, I think with possibly one or two exceptions, I did not personally select the superintendents for the compressor stations. I did know every man selected, however, knew of his training, of his qualifications and experience and I had a judgment as to whether that man would be qualified or not; but in the selection of those men, as far as possible, I leaned towards the recommendations of the compressor station superintendent in Chicago who was to have charge of those men and tried to delegate as far as possible, or make him feel that responsibility as far as possible by letting him select his own men. There were disagreements and there were differences of opinion, but in very few instances was it necessary for me to veto the recommendations of that man.

Now the same thing applied to the pipeline division, telephone division and the production department. Having selected the head of each one of our operating departments, field and office, I then tried to delegate to the man selected the responsibility of picking his key men. You can see therefore that I did not mean to convey the impression that I had selected the 500 men who form our operating company.

As a matter of fact, the work of building this organization was done primarily by me, then by the members of my staff, and then in turn by the members of their respective staffs clear on down through the organization, so that the time of a number of us was devoted to the selection of the organization. At this point, I want to say in order that the record may reflect the fact, that the key men, the staff men in the organization, were as much responsible for the success attained by these companies as any success I might be claiming here for the picking of this organization of which I think so highly.

976 As an example of the way we work, since we last met in Chicago, one of our station superintendents, the superintendent of number 3, died very suddenly. That immediately called for the replacement of that superintendent, either by a man immediately under him at the station or the transfer of a man within the company from wherever we felt that we might have that qualified man available. If he is not within the company, we have got to go on the outside. It is seldom that we ever—and I do not recall a single instance where we ever have—go on the outside to pick a man for an important position, as important a position as a station superintendent. Those men are trained from within the organization.

When this superintendent died, we immediately considered the list of men which we have and which we are constantly considering, the men who are available for promotion into other positions. Mr. Kesinger, Mr. G. M. Davidson, Mr. Walt Davidson, and I reviewed the list. They first conferred and decided upon their recommendation as to who was to fill that vacancy. That man was considered and agreed upon. We then considered who would fill the vacancy created by the promotion of that man. Well, progressively, before we got through, the result was that about 5 men were advanced within the company. We try to build and train for advancement our own men, not only because we feel that it has certain incentive value, so that these men may know that they are in line for promotion but these men have been definitely viewed for a period of months or even years and are considered to be second or third string men in line for promotion to positions of responsibility. In the meantime, we have seen to it that they are acquainted with the responsibilities which they are to assume when that date of promotion comes. While it is not easy to overcome the loss of a man of that capacity, we nevertheless are trying to follow an organization procedure which will enable us to build and take care of emergencies such as that when they arise.

In a system of this character involving the dangers and the technical difficulties that are involved in the operation of a business like that of this pipeline system, all positions are responsible positions. The degree of responsibility may be relative, and we may be inclined in our routine discussions, to speak of our supervisory staff as being the men of responsibility in our company. It is true we like at least to feel that we occupy some position of responsibility in the company. Yet, we are not unconscious or unmindful of the responsible position played by practically every man in the company, whether he is charge of 10 men or whether he is responsible for only his own efforts.

Take a pipeline welder, engaged in work typical of the work we are now doing, where we are welding sleeves over these rubber couplings. These men are welding a heavy plate of steel, a drop forging, to the pipeline while the pipeline is in operation. This pipeline carries pressures up to 710 pounds per square inch, with a daily flowing capacity of 210,000,000 cubic feet per day, and is continued in operation while this welder is raising the wall of the pipe to a fusing heat to weld the sleeve to the pipeline. That is not work that we can entrust to an ordinary welder or that the average welder can do without the most careful training, observation and experience as a welder's helper. When we are raising a pipeline under 710 pounds pressure to a fusing heat to weld a sleeve to it and keep the pipeline in operation, we are playing with something that is more dangerous than dynamite. 977 Yet, that is an every day operation that we are performing. It is also performed frequently where leaks occur. Not only is this a part of our operation in this construction program of welding sleeves through flood valleys to try and reinforce the line, but that is typical of the type of man that I say occupies a responsible position with this company. It requires not only training but it requires experience—experience that is not attained on the average pipeline— This organization has to have men thoroughly acquainted with the hazards of operating at these pressures. The improper closing of valves, closing them in the wrong order of sequence, when we are working on shut-outs, and so forth could cause the explosion of the line or an explosion in the station, endangering the property of the defendants and the lives of many people.

These men can not be picked up from the outside. We can get good gas men, yes; but we can't get men who have received the training and experience that this organization has had from the date the pipeline was started, through the some 9 years of its operation. These men are not just ordinary men. When we have a shut-out or an emergency arises as a result of a break in the pipeline and air gets into the pipeline, extreme care must be exercised to see that the air is excluded and that the line is thoroughly purged of air before it is placed back in operation. If this air is allowed to become locked up in the pipeline with the gas when the repair is made, we then carry an explosive mixture which may let go in one of the compressor stations or in the home of one of the consumers. We are dealing with a dangerous commodity and we are dealing with pressures and facilities here which do not occur in the ordinary natural gas pipeline transmission system.

I have already spoken briefly of the way in which we attempt to keep in mind promotion of our men and the training of these men through progressive steps. We try to ascertain or determine from the traits shown by a man and his apitude for the type of work whether he is best suited for the office or for field duty, whether he seems to have more apitude and a greater possibility with the pipeline department or whether he is of that mechanical type that would prove more efficient around the compressor station. Having ear-marked these men, we try to put them in a line of training progression, so that they are fitted for these positions when vacancies occur and we like to think of them as second and third-string men. They might even be serving as assistants, or they may not bear any title but are under the scrutiny and close observation of our supervisory staff. It is not infrequent that we will get together with our field and office supervisory staff and talk over the qualifications of these men, how they are coming along and whether they are ready for promotion when vacancies occur.

There are two channels through which we get men into the organization in the first place. I do not mean to convey the impression that every man we have is a technically trained man and yet I doubt that there is an organization along the natural gas transmission system which so thoroughly stresses the importance of employing technically trained men and insisting upon technically trained men occupying supervisory positions as have these companies. I am intimately acquainted with the top executives of practically every natural gas pipeline company operating in the United States today. I have supplied to those companies a good many men from my organization when I was with the Empire Companies. Some of my men were attracted to some of those companies since that time through larger salaries or promotions which I could not give them in my own organization. I know 978 the field men and the office men in those other companies. It is not hearsay. In addition to that, I have had occasion many times to talk with the top executives in these other companies as to the type of men that they are employing, the type of men that they are training, their training methods, where they secure their new material, and have been frequently requested to explain to them how we go about securing our graduate engineers and training them for these positions of responsibility. Our men have attracted attention throughout these other organizations because of the methods we have employed. They are not employing those same types of training methods. These exchanges are not purely casual. Quite often they become a matter of a roundtable conference at our Natural Gas Conferences each year. We have two of those. There is a general session to the fall and one in the spring. The spring conference is confined to natural gas activities; the fall conference to both natural and artificial gas. We make a systematic effort to find out what the other companies are doing in the matter of training their own personnel in order that we may take advantage of whatever improvements they make. (Objection of Commission's Counsel to entire line of questioning overruled.)

We select our new material as far as possible from the engineering graduates of schools bearing good engineering reputations and these men are brought into the company. We take in a new group each year. It may be only a few men, it may be a larger number, depending upon our needs. These men are selected carefully and brought in each year, but I think it is not necessary to go into detail for as I recall this question of training junior engineers has been discussed in the past. They are placed in a training course with the company and this course extends for a period of two years. After having had a foundation of engineering and two years of schooling in the intricacies of the companies' operations in field and office, they are then in a position to take positions of responsibility and to progressively work up through to supervisory positions as vacancies occur.

We have in our organization occupying staff positions men who have been through this type of training known as the junior engineering course. If for any reason we were to lose our organization and were confronted with assembling another organization to take over the operation of this plant in the period of 30, or 60, or 90 days, we would have to shut down the pipeline. I do not think that there is any reasonable probability of the company losing either 500 men or 50 of its most important men today and being required to replace them in 30 days. (Motion to strike the witness' testimony by counsel for the two Commissions denied.) We could not possibly man this pipeline with new men whether they be routine laborers or operators or executives in 90 days and put it in operation again. We could carry some gas and we could start limping along in operation; but we are dealing with high pressures, with mechanical facilities extending over 900 miles here. The very lack of knowledge of the facilities themselves would prevent inexperienced natural gas operators from putting this system into effective operation in 90 days. It would demoralize the whole organization. It would not take months but years to really qualify these men to become efficient in the handling of the company's facilities and its properties. Our men have grown up with this company and much of their value is attributable to their experience and knowledge that they have acquired in the operation of this company's properties. These field men know every foot of the pipeline. They know the treacherous and dangerous conditions, where they are and where they have to be watched for, the areas where, after a heavy rain, the maintenance staff immediately has to go out and patrol the line to take care of wash-outs and backfill the line where the cover has been washed off. The areas through

Iowa are particularly bad in this respect. We have other areas that we know are subject to flood and where 979 other types of danger make it necessary for the men, through their experience gained over years, to get out onto these properties and to get out quickly. These men have acquired that knowledge in the past 9 years. They know the farmers, the farmers' phone numbers and they know in the event of an emergency they can get in touch with the farmers and muster forces of an additional 100 or 200 men that we can not keep on our payroll to take care of the emergency when it arises. They know the public supervisors and have established contacts which enable them to obtain the road equipment, the trucks and so forth, and that is available to us only through knowledge and experience gained over this period of years. A new staff could not come in and take over the property and do all these things.

The same thing is true in the office. Our office staff knows the companies' history, contracts, their negotiating problems and litigation. It would be impossible to move in a staff of men who could come in and take over the books and affairs of the company who are not experienced with the history of the company. So part of the value of our men has been gained through long years of experience and knowledge acquired through those years of the companies' affairs. (Objection by Commission counsel to Examiner's ruling as to time within which to complete corrections to transcript, and objection by counsel for Illinois Commerce Commission to the number and character of corrections submitted by Company counsel.) I do not think that I would want to undertake the responsibility of assembling an organization of the character of our present organization and report to the owners of the company that it could be accomplished without a cost of ~~$200,000 or $300,000~~. It would mean a substantial reduction in the operating capacity and the efficiency with which the facilities could be handled. The facilities would be manned with men inexperienced in the companies' properties and it would mean the elimination of operation with experienced men and pursuing a cut and try process of drawing a man here and there until the right men had been found. Now this is always expensive. The turn-over of any organization is expensive and there is always the danger of serious accident and damage. I would say it would cost a very substantial sum of mony. (Objection by Commission Counsel overruled.)

At this point, counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company—Personal Data." At the Examiner's direction, the document was marked Exhibit 129 for identification.)

I have before me a copy of Exhibit 129 for identification. That document contains a skeletonized personnel record of a number of the top executives and the supervisory staff of these two companies. Let us take page 1 and analyze it very briefly. We set out in line 1 the name of the man, the position he occupies, his age, education, that is the field in which he was educated, the time which he has been with the company, the experience in the present line or with this character of work. The facts dealing with experience are broken into three parts, showing the position, the employer, and time of employment. It also shows the different positions he occupied at subsequent dates; the term "employer" covers all of the companies down to and including his present employment and the length of time with each employer is set out in the last column. It will be noted that with few exceptions, the men composing our organization are below the age of 50 years, although they have had the experience set out in this exhibit. In my judgment, there is an advantage of a substantial character in having an organization manned with young men who are conversant with their duties. These men with their technical training and years of experience and who have not acquired
980 in the majority of cases an age of 50 years have many years of usefulness before they reach a retirement age, so that the company will continue to enjoy the advantage of their mature judgment, experience, and long association with the company.

This list does not show all of the men who can be classified as executives and staff men. It is extremely difficult in the preparation of a list of this character to know just where to stop. We reach a point where we are trying to terminate the list and the next man below is just as important as the last man included and yet we have to stop somewhere, otherwise, we would list almost the entire personnel of the organization. I did not realize until I was looking over the list last evening that the name of our chief accountant, Roy Miller, who is to appear as a witness this week had been left out. Yet he is equally as important in this organization as any man on the list. Some of these men are the same men who have testified as witnesses in this case and others will appear as witnesses. (Objections by counsel for the two commissions overruled.)

In my judgment, the fact that we have an organization selected, trained and assigned as to its members to the particular positions which they occupy clear through the entire organization gives an added value to the properties of these companies over what they would have if we merely had the physical properties and had no such trained organization but had the task of training the organization before us.

Cross-Examination by Mr. Booth.

I have been in direct charge of the operations of these companies practically from their formation. I have been responsible for the operation of these organizations. The companies have a president. He sits as the Chairman of the Board of Directors but as to the operating problems, the day to day operating problems of the companies, I decide them. I do not think I could say offhand what policies he personally decides. Matters that are not decided by the organization in Chicago are usually passed upon by the board of directors rather than by the president acting alone. The president of the companies does not draw a salary from either of the companaies. Ordinarily in any organization it is not the president of the organization who decides its principal day-by-day important operating problems. I have testified that I have a good deal of experience and know the operations of other natural gas pipeline companies, and that I was acquainted with the officials of those other companies. I have not attempted, in my testimony, to state what the functions of the officers of those other companies might be. The function of the president of a corporation varies a great deal in different companies. In some companies the president, because of the nature of his training and experience, will confine himself to the financial and corporate side of the business. He may have and often does have a vice president and general manager who is an engineer and trained by experience for operations and the president will delegate to him the operating responsibilities. In other instances, the president may be the operating man and he may fortify himself, or supplement himself, with perhaps an attorney or with a man who is acquainted with the corporate, legal and other side of the business. I do not think the duties of the president of these companies have ever been outlined by the board of directors. As I have said, his function to a very large extent is to sit as the chairman of the board of directors, when matters which are of sufficient importance to take to the board of directors are under consideration.

These companies maintain a retirement plan which we recently instituted. I think it was as of September 1, 1938. This grew out of a composite effort engaged in by the secretary of the company, the tax counsel, the chief engineer and the general superintendent. I had something to do with trying to help formulate a policy which would be applicable to the needs of the company. I am not prepared to say why this plan was not put into effect in 1933.
981 Writing of retirement plans was not actively engaged in in 1933. I think that the efforts of the government in trying to provide retirement plans has stimulated the interest of corporations with the result that there has been an epidemic, if I might so term it, of retirement plans and methods by corporations in all lines within the last two or three years. We were fortunate in the writing of our plan in having available the many, many plans of different corporations which had been written within the last two or three years. The interest of our employes was stimulated. There was a clamor, a demand, for this type of protection. It is no different than group insurance. It is a plan which the companies have all felt had certain definite tangible value in helping to maintain a satisfied group of employes.

It is true that the companies up to December 31, 1938 paid approximately $9,000,000 in dividends on their common stock and during that same period they set aside only approximately $30,000 for a retirement plan to take care of its employes. None of the expenditures of the two companies in connection with the training of the employes was charged to capital account. These expenses were charged to operating expenses. These companies laid out no money for the training and experience of their men obtained prior to the time they became employes of the two companies.

(At this point EXHIBIT 129 was offered and received in evidence without objection.)

982 J. A. EMERY, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(September 6, 1939.)

My name is J. A. Emery. I live in Montclair, New Jersey. My place of business is in New York City. I am senior vice president and member of the executive committee of Ford, Bacon & Davis, Incorporated, an engineering firm. This firm was established in 1894 and conducts all classes of engineering.

I received my technical education at the Massachusetts Institute of Technology in civil engineering. For several years after leaving college, I was engaged in engineering design and management of construction principally for electric railways and railroads. I began my connection with Ford, Bacon & Davis, Inc. in 1898.

Our firm is engaged in engineering of all descriptions, including surveys and reports, design, supervision and inspection of construction, management of construction, contracting, financing, valuation, and purchase and sale of properties for both public utilities and industrial concerns. I should have included also the operation of business enterprises including natural gas companies in the operation of which they have engaged rather extensively. They have appraised all kinds of properties, railroads, electric railways, electric light companies, gas properties both artificial and natural, industrial properties, and commercial properties. These valuations have had to do with intangible as well as tangible properties.

The connection of my firm with the natural gas business began to the best of my recollection in 1907 when they made an extensive examination of the natural gas properties owned by the Philadelphia Company which operates in Pittsburg and in the vicinity of Pittsburg. These natural gas properties included production properties in Western Pennsylvania and West Virginia, together with transmission lines. The report was made for a syndicate who were considering the purchase of the company. They afterwards made the purchase.

The firm was employed in about 1910 to make a study of the introduction of natural gas into Baltimore. In 1913, a report was made on the Union Gas Company which was located principally in the southern part of Ohio and is now a part of the Ohio Fuel System. In 1920, the firm began a series of valuations of the East Ohio Natural Gas Company, operating in Cleveland and in Northeastern Ohio; the Peoples Natural Gas Company operating in Western Pennsylvania and West Virginia and Hope Natural Gas Company operating principally in West Virginia.

In 1925 a preliminary survey and later a complete survey were made of the gas project in Alberta Canada to serve Edmonton and the surrounding district. The firm made complete designs for this system, supervised and managed the construction and had charge of its operation for a couple of years thereafter.

In about 1926, the firm engineered and supervised the construction of a line from the Monroe, Louisiana gas field to Baton Rouge. That line was followed by lines to St. Louis, Memphis, Birmingham, and Atlanta. On all of these, the firm made the designs, inspected the
983 construction and in the case of the Interstate Line in Louisiana and of the Southern Natural Gas Company which ran to Birmingham and Atlanta, it conducted the operations for several years.

It also engineered, supervised the construction of and had charge of operations for several years of a line from the Texas Panhandle to Denver, known as the Colorado Interstate Line. It also made a report on the West Texas Gas Company and its affiliated company, the South Plains Gas Company, which take their gas from the Texas Panhandle field. The firm also made a survey and report of the natural gas market in Philadelphia and in northern New Jersey, the latter covered practically the whole northern half of the state which is the territory served by the Public Service Electric & Gas Company.

In connection with the work of my firm and in my capacity of one of the chief executives of that firm I have to do with the operating problems such as load building, and things of that character. In the course of my work over the years, I have had occasion to examine the operating records of natural gas companies, I am familiar and can interpret that kind of record. I have not been intimately familiar with the Panhandle gas field in Texas. The firm has not done a great deal of business in connection with it and I am only generally familiar with it. It is my understanding that it is one of the greatest gas fields that ever was discovered.

I am familiar with the pipeline company known as Natural Gas Pipeline Company of America and its companion company Texoma Natural Gas Company. This system obtains its supply of natural gas altogether from the Texas Panhandle Field and sells it principally in the Chicago district, but to some extent in the State of Illinois, west of Chicago, in Iowa, Nebraska and Kansas.

For the past 18 months, I, with associates, have been engaged on a study of these companies for the purpose of making an estimate of their going concern value and of considering the reasonable rate of return which would attract the capital necessary for their construction. I have studied the record of these companies and their history for the purpose of determining those factors which I deem pertinent to the consideration of their going concern value and rate of return. They have made available to me their books of account and their official records. Through my staff, I have made a detailed examination and inquiry into the facts to which I am about to testify.

From the investigation, I note that this pipeline system did not start out about the first of the year 1932 with a full load of natural gas. That is not unusual. In fact it would be unusual if one should start off with a full load. The company must convince the prospective customers that its service will be reliable. There is always a reluctance on the part of people using one fuel to change to another and the advantages of the change have to be very definitely pointed out to them. That is not a thing that can be accomplished over-night. It takes several years to build up a load. In the case of these companies, it took about 4 years to do that.

I have had occasion at different times to make a great many different studies of industries, population, and so forth, in Chicago and in the Chicago district but I have no very intimate knowledge of the conditions on those parts of the line in Western Illinois and across the states of
Iowa, Nebraska and Kansas, where Natural Gas Pipe-
984 line Company disposes of a part of its gas. My knowl-
edge is not more than general.

I have treated the two companies in my study as one system, they were projected and constructed as one system; and they are under the same management. They are largely owned by the same interests. The pipeline is dependent upon the producing company for its supply of gas to the extent of 75% thereof and the producing company is dependent upon the pipeline for its market. They form one continuous system. While the pipe line takes ¼ of its gas from another company, the Canadian River Gas Company, it is dependent on Texoma in the sense that the Texoma company guarantees the future supply of the pipeline.

I have examined the corporate set-up, the assets, the operating expenses, fixed charges, revenues, and attendant facts connected with the operation of these companies from the beginning of their operations and have had the figures carefully analyzed, so as to be familiar with each of these companies and its operating costs and expenses. Our analysis was for the purpose of determining, first, the going concern value and second, the rate of return to which these companies would be entitled.

When the materials for a property of this kind are assembled and put in place, the property is by no means ready and able to furnish the service for which it was projected. It is necessary to go through a considerable amount of promotion and expense before the property can be brought to a position of standing on its own feet in giving the efficient quality of service that is necessary to justify it financially. This means that an operating organization must be formed, drilled and perfected, that the forms and records necessary for efficient operation must be carefully worked out and tested, the physical property must be what I call "seasoned", that is hidden defects at the close of construction must be corrected and the full volume of business for which the line was built must be attached.

I consider going concern value to be the difference in value between the inert physical property as it would stand at the close of construction or reproduction and the property in full operating momentum with an efficient trained personnel, thoroughly seasoned and with the full complement of business attached. I want to add that I think in considering the going concern value of a property of this kind, the character of the territory in which it is located should be taken into account, that is, whether or not it is thriving and has prospective stability. In other words, I think that a pipeline system equipped to bring natural gas to Chicago and prepared with its organization and other things necessary to bring natural gas to a center of population like Chicago should be worth more than a pipeline built out in the semi-desert area of Arizona, even though it had the same type of physical property, the same investment in the property itself and both were taking gas from the Texas Panhandle field.

It would be extremely uneconomical and impractical to start out with only the facilities necessary to handle the load for which a market is obtained in the beginning of operations and then add to the capacity from time to time as the load is built up over the years. After a pipe is once laid, the size of it can not very well be increased, of course another line can be laid, but if the line is laid only large enough each year to take care of the increase in business each year, you would have a very uneconomical sys-
985 tem. The more economical, as well as the more prac-
tical, thing to do is to provide the facilities at the beginning which are necessary to handle the load which it is expected to acquire over a reasonable period of time. There is expense involved in the building up of the load to the full capacity of a pipeline system like that here under consideration. In the first place, the mechanical cost of attaching the business must be taken care of. By that I mean, the soliciting of customers, the negotiation of contracts, the advertising, and the changing over of appliances, to name some of the items of expense.

Also, there are the fixed charges on that portion of the line so provided and the operating expenses which can not be proportioned to the volume of gas but are proportioned to the size of the physical property. By the latter, I mean the operating expenses which are incurred from the beginning and which continue on regardless of the quantity of the load as distinguished from those which are added as the load goes up and the volume of gas handled is increased. There are certain operating expenses which have to be assumed in full when the operation starts. The fixed charges to which I refer as being constant and which involve an actual outgo of money to the companies in connection with facilities provided before they are required to handle the full load include return on investment or rather, interest on the investment, depreciation, and taxes. and dividends whatever return is called for on the remainder of the investment in excess of the bonds. I do not mean interest that accrues as a matter of bookkeeping because the money is tied up but only the interest that is actually paid out. In figuring up the costs to these pipelines for providing the facilities in advance, in terms of money actually paid out, I have given consideration to interest, depreciation and ad valorem taxes. In the case of these companies, the period of load building extended over a period of about 4 years, that is from the first of 1932 through the year 1935.

In connection with the attaching of customers or persuading prospective customers to purchase gas, it is necessary to set up forces of negotiators, a new business department, and the higher officials of the company must devote a certain amount of their time to such work. There are traveling expenses and supplies but the greatest item is that of contributions for changes in appliances which are necessary to induce customers to change over to natural gas.

I have been furnished with a statement of the actual expenditures during this 4-year period and the commitments made during that 4-year period in connection with their load building. This is in such detail as is reflected in their operating expense accounts. These companies actually paid out in the solicitation of business by years the following amounts:

1932	$ 86,105
1933	219,149
1934	889,060
and 1935	373,477

the latter amount includes $65,471 paid out in 1936 but contracted for in 1934 and 1935. The total is $1,567,791. In my opinion, these amounts aggregating the amount just stated, represent a portion of the expenses to which these companies were put to obtain its going concern value.

The other direct costs that are chargeable to the attaching of business, or the making up of the going concern value, are the fixed charges on that portion of the physical property provided in advance of the full attachment of the business for which they were built. I mean the interest, depreciation, and ad valorem taxes on the property of these companies that made up the project. In arriving at
986 the proportion of this interest, ad valorem taxes, and
depreciation and costs of operation, chargeable to the cost of attaching business in helping to make up the going concern value, I considered that a fair standard for judging the capacity of the property could be obtained from the load carried in the years 1936, 1937, and 1938 when the load had been built up to what I call the capacity of the line.

That capacity, if running full all the time, would have been 210,000,000 cubic feet per day, or 76,650,000,000 cubic feet per year. These companies never actually ran that much gas. They actually ran in the 3-year period I have taken an average of 92.48% of that quantity and I have considered the amount they actually ran to be the standard of full load. It is not possible for a natural gas pipeline company to deliver 100% of its capacity every day of the year as a practical business proposition because of the variations of the demands of the customers. For instance, a househeating load is comparatively large in the winter months and amounts to nothing in the summer months; also there are days of the week when the industries are utilizing more gas than other days and variations of that sort.

I have taken this 92.48%, which was the per cent of the total capacity of the line that it was able to deliver during the three years after it was first loaded, and have used that as the standard. However, the original capacity of the line was not 210,000,000 cubic feet per day but 175,000,000 cubic feet per day, or 63,875,000,000 cubic feet per year. In determining the extent of the excess facilities over those actually in use in each year of the load building period, I have compared the actual volume of gas delivered with the capacity based on the load factor which was found to be practicable in the years 1936, 1937, and 1938. That is, I have taken the capacity of running full in the load building period and have multiplied that by 92.48% to obtain the practical maximum capacity of the line and then I have compared that figure with the actual volume of gas handled in each of the 4 years. In other words, I have used 92.48% of the rated capacity of the line as the basis of comparison and have compared the volumes actually put through the line to that basis.

In 1932, I found a lag of 51.98% which means that practically 52% of the property for that year had been provided in excess of the business attached that year. In 1933, the lag was 56.75, in 1934, 21.42%, and in 1935, 3.63%.

I have ascertained the interest that was actually paid out for money which went to provide those facilities of the system. I got these figures from the records of the company. The interest paid out in 1932 amounted to $3,666,350, in 1933 to $3,625,079, in 1934 to $3,598,329, and in 1935 to $3,474,732; a total for the 4 years of $14,364,490. I have applied to those figures representing the interest actually paid out each year the percentage of lag in attaching business during the same year, with the result that for the year 1932 I took 51.98% of the total interest paid out, which resulted in $1,905,769 paid out on account of facilities provided in advance of the load. By the same process, I found that the interest paid out on account of facilities not yet in use for the year 1933 was $2,057,232, in 1934 $770,762, and in 1935 $126,133, making a total for the 4 years of $4,859,896.

987 I then determined the ad valorem taxes paid out on account of facilities owned by these companies each year during the same 4-year period.

(At this point, counsel handed the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Cost of Attaching Business—Witness J. A. Emery" and asked that it be marked as an exhibit for identification. At the direction of the Examiner, this document was marked Exhibit 130 for identification.)

By ad valorem taxes, I mean taxes generally on the estimated value of the property, that is taxes that the various taxing bodies levy on the property itself as opposed to production taxes, franchise taxes and other taxes of that character. I find that these companies paid out, during the 4-year period of the load building, ad valorem taxes as follows:

in 1932 $301,776
1933 301,629
1934 270,558
and in 1935 289,193, a total for the 4 years of $1,163,156.

I applied the same percentages of lag I had already determined and which I applied to the interest payment for each of the 4 years and in that manner arrived at the amount of taxes which were paid out on facilities provided in advance of the loan. I found the taxes on facilities not yet loaded for the

year 1932 to be $156,863
1933 171,174
1934 57,954
1935 10,498, making a total for the 4 years of $396,489.

I then made the same character of calculation on the depreciation as determined by Mr. Biddison in his recent survey of the property and referred to in his testimony.

I mean the actual viewed depreciation of the physical property as determined by Mr. Biddison. The basic figures were furnished me by Mr. Campbell, the Secretary of the company, who started with Mr. Biddison's figures. I have assumed that the depreciation was uniform from year to year from the beginning of operations until the time of Mr. Biddison's inspection, consequently, I have divided his findings as to depreciation by the number of elapsed years. That amounts to $386,529 for the whole property as he found it for each year.

I applied the same percentages of lag to these depreciation figures as I did in the interest and ad valorem tax figures and obtained as results for the

year 1932 $200,918
1933 219,355
1934 82,795
1935 14,031, making a total of
$517,099.

988 Viewed depreciation is defined as the loss in value of the property, and even if it was not paid out-of-pocket it all constitutes a liability which will have to be paid some day. It is a loss which is incident to the natural deterioration of the property. That loss occurs largely without regard to whether or not it is being used to its full capacity or to only a percentage of its capacity during the earlier years of its history. This is the item of depreciation which, in computing the value of the property and approaching that subject from the standpoint of reproduction cost new, must be deducted from that reproduction cost new in computing the value.

Now this other item of cost of operating facilities provided in advance of attaching business, I computed in the following manner; there are certain operating expenses which must be incurred when operations begin in substantially as great amount as later when the line is loaded. I considered that the proportion of such expenses in accordance with the estimated lag in load is attributable to going concern value. These were operating costs that covered the unused as well as the used portion of the capacity during this period of load building.

I took the production department expenses, other than gas royalties and taxes on gas produced, the mail line expenses, the telephone department expenses, and the general expenses as recorded, other than taxes. I did not include any of the expense of operating the compressor stations although a part of that might reasonably have been taken. My reason for not including any part of the compressor station expense was that there may have been some items which in part should have been omitted and I considered that by omitting entirely the compressor station expense and the gasoline plant expense I was fully making up for such items and arriving at a fair figure. I found that during those 4 years, those items of operating costs that I have taken into account are fairly uniform in amount year after year except in the first year when they were substantially higher. The first year, they amounted to $1,072,759 as compared with $835,903 the next year and comparatively the latter amount for the following years. That higher cost the first year was due to non-recurring expenses which, although I do not have the details, must have been in the nature of perfecting the personnel, preparing the operating forms and procedure, and seasoning of the property.

By "seasoning of the property", I mean consummating the back fills, making provision against wash, as it appears after the line is completed and placed in operation, riprapping, and other measures which have to be taken at the river crossings, and alterations in the compressor machinery, and items of that kind. I did not try to pull out these items attributable to seasoning from that large operating expense of the first year but left them in and applied the percentage of lag to the whole amount. Had I been able to pull out those items which represent seasoning I would, instead of applying the percentages of lag to them, have put them all in as a part of going concern value. So by leaving them in this item the amount of the cost is reduced by the difference between the percentage of lag and 100 per cent. (Motion by Commission Counsel to strike the above testimony denied.) I stated earlier that this difference in the aggregate amount of these charges, which do not vary with the load between the first year 1932 and succeeding years, was made up of non-recurring costs which I have attributed to seasoning. Then I went into the record and took these items one by one and pulled them out, that is all of such charges instead of just the 51.98% attributable to lag would have been properly included as cost of obtaining going concern value.

That is all of the excess of such expenses in 1932 over the corresponding increases in the succeeding years 1933 and 1935. To get an exact figure, I would take the average expenses for the three years as the normal amount, although the differences are not large.

Applying the same percentages of lag to these op-
989 erating costs, I find that the operating expenses incurred on account of facilities provided in advance of attaching business for the

Year 1932 to be $557,620
1933 474,375
1934 165,066
1935 29,757, making a total for the 4 years of $1,226,818.

As appears in line 1 of page 1 of Exhibit 130, the items attributable to the capacity provided in advance of load are interest, taxes, depreciation, and operating costs, amounting to a total of $8,568,093. In that amount is included no interest that was not actually paid out on account of the facilities provided in advance, nor were there included any taxes not actually paid on account of such facilities. I have used the figures representing the actual physical depreciation of the properties not yet in use during the load building period.

As I have already stated, there are other expenses that would have to be incurred in connection with the building up of the load and putting the project on a going basis or putting the wheels to turning in the sense that I have expressed it here.

The organization, as we find it today, has a value must greater than would be that of any crowd of men that could be assembled hurriedly. It has had the benefit of a number of years' familiarity with the property, with the territory, and with the customers. These men know how to work together. This excess of value is reflected in the efficiency of operation. In other words, an efficient organization can operate the properties more cheaply than a less efficient organization. It is not possible to assemble an organization of this kind without substantial expenses and that expense has got to be borne by someone somewhere down the line. I am acquainted with some of the personnel which operates these properties. I have made a point of meeting and sizing up the principal executives, including Mr. Brown himself, and my associates have done the same thing. I have known Mr. Brown, Mr. Kesinger, and other operating heads and executives over the years. I heard Mr. Brown's testimony here today concerning the type of organization that he has. His testimony coforms to my understanding of the type of men who are employed by these companies.

In my opinion, it is an excellent organization which adds a value to the properties of these companies over and above the value which those properties would have without the organization. It has that value because it would cost money to reproduce it. It would cost money to put it where it is. It adds a value to the use of the property because the latter can be operated more cheaply and it certainly would be taken into account in the matter of exchange, purchase and sale by a purchaser who was interested in buying the property. Of course I cannot tell how much.

To make an organization of 600 men work efficiently together, their duties must be carefully defined and understood. That is accomplished by means of instructions which are sometimes worked out piece-meal. Often it is done by instruction books for various departments. I understand that it has been done for this company entirely in piecemeal. To obtain the greatest efficiency of op-
990 peration of the physical property, records of performance have to be maintained very much similar to laboratory records. These records have to be prepared in such a way that they can be understood and that the results can be obtained from them readily so that they can be summarized for the constant inspection of the higher officials. These companies, I find have over 300 forms used in their operations and the very process of designing and perfecting these forms would be expensive and it makes a great difference in operating expenses whether these forms are efficiently designed or not. If the forms are so designed that false motions are made. It means a multiplication of such motions day after day throughout the year.

It is not possible for a business of this magnitude to anticipate and prepare in advance all the books of account, tax records, performance records of the machinery, ad the procedural directions that become necessary as the business is developed and those operating it become acquainted with its details, or a lapse of time and considerable expense are required. Of course if you previously had exactly the same kind of company that was performing as well as you would expect it to perform, where special attention had been given to the subject, you could obtain a satisfactory series of forms at the beginning, but no two companies operate alike and the only way in which the best system of forms and records can be devised is to study it out. (Objection by Commission Counsel.) I have made estimates of this cost but no such estimates as I would feel that I have checked over carefully enough to present. (Objection overruled.) I did not say that I have made estimates in other cases, but I meant that I have made an estimate in this case, but I have not checked it over sufficiently to be satisfied enough with it to present it here. In other cases I have made estimates of a specific value to that element. It would cost a substantial sum of money to reproduce these forms, records and procedural documents. I consider that the location of the company in a thriving, growing territory gives it an element of value, but I have not attempted to estimate how much that would be. But I have always tried to consider a value as a single figure and not that in the case of a property there could be a value for one purpose or another. I am aware that the purpose of determining value in this proceeding is solely for the purpose of rate-making. It is my personal opinion that a company is entitled to an element of value for rate-making purposes only insofar as it has contributed to that condition, which a company often does by fostering the territory, that is, building up industry.

Based on my experience and observations over all these years, I do not think this pipeline system could have overcome the difficulties of loading its pipeline within the period that was required had it been built for a less favorably situated outlet than that of Chicago and those places along the line where it has markets at so small an expense. It could not have been loaded in the same time at the same expenses.

The valuation of the going concern element of a company is a matter of judgment. There is no exact method of calculation. In arriving at your judgment or opinion of such value, it is customary and proper to assemble, weigh, and hold in view all the evidence relating to such value. In this case, I have analyzed the going concern value as I see it, and I have taken such items as I felt could be definitely determined from the records of the company as having been paid out. That gives me the cost of such elements. Now "value" is not cost, but I have chosen to leave out all the other elements of value which I have enumerated and estimated the value of the going concern value of this property as the sum of those figures which I have derived as the cost of certain parts of the going concern elements. This sum aggregates $8,568,093 and in my opinion, the going concern value of this property is not less than that. That is the figure indicated in Exhibit 130, page 1, the item in the lower, extreme right-hand corner. (Motion by Commission Counsel to strike above testimony overruled.)

Based on by experience in the design, construction and operation of pipelines and the problems that are encountered in connection with such operations and with the loading of the pipeline or building up the demand upon it to the point where it can not be loaded any more, it would cost as much if not more to reproduce the elements entering into my judgment just expressed as to the going concern value of these properties. (Motion by Commission Counsel to strike above testimony overruled.)

991 I obtained the figures as to the sales and the operating expenses set out on pages 2 and 3 of Exhibit 130 from Mr. Campbell, the secretary of the company. The analysis shown on page 2 and page 1 are my figures based on the figures furnished to me by Mr. Campbell.

Cross-Examination by Mr. Booth.

The evidence that I have given is that the cost of these particular elements is as stated on that exhibit, based on that cost for certain of the elements, I should estimate the value of all of the elements at not less than that amount. In other words, that is the proper and reasonable amount of going concern value that should be allowed for these companies in this case. The going concern value includes not only those elements set forth in Exhibit 130 but also the elements I have discussed. I made no estimate of either the actual cost of those other elements, the cost to reproduce them, or their value in use. I cannot say without more consideration whether I would still reach the conclusion that the going concern would be $8,568,093 if these other factors not included in Exhibit No. 130 had not existed. As to whether I will say that these other elements form a small or large part of the 8½ million dollars, I do not know what is meant by "large" or "small". In this figure of $8,568,093, the cost of assembling the organization, the accounting procedure and the favorable location had nothing to do with the size of the grand total cost of attaching the business. It includes simply the items contained on page 1 of Exhibit No. 130. I would not reach my conclusion that the Company was entitled to 8½ million dollars independently of these other factors, nor would I if I had not made the study shown on Exhibit No. 130. I spent approximately 18 month off and on in making this study of going concern value.

My study of this going concern value has continued over a period of 18 months off and on, not continuously. I think the time actually spent would represent 5 or 6 months of continuous work, not by myself but by members of my staff. I am familiar to some extent with the operations of other large pipeline companies that have as their source of supply the Panhandle field in Texas.

I am not familiar with any of the details of the Panhandle Eastern Pipeline Company's operations as to the cost of building up its load. My only information about it is that it has taken much longer to load it than it has this line, if it is fully loaded now. Other large pipeline companies which have the Panhandle field as their source of supply are: the Colorado Interstate, the Northern Natural, the Cities Service, the Panhandle Eastern and the Lone Star Gas Company. I have made no study of these lines from the Panhandle field. I did take account of the expense of the Alberta Company where the company began from scratch.

I spent considerable time developing the theory upon which Exhibit 130 is based. I did not discuss it with Mr. Hamilton. Nobody suggested to me the use of these various items which make up Exhibit 130. It is a development of the work we have done on this subject extending through a good many years. That exhibit constitutes a summarization of the work we have done on the subject of going concern value for these companies. In my judgment, that Exhibit 130 and the testimony explaining that exhibit constitutes the principal or major basis for my conclusion that this company is entitled to a going concern value in the amount that I have stated.

Cross-Examination by Mr. Slaff.

I am acquainted with Mr. Hamilton of course. He has testified in this case. I have known him a good many
992 years and know his professional standing, the type of work he does and so forth. In reply to your question, in which you have stated what Mr. Hamilton testified to as a reproduction cost of these properties and the amount resulting from the deduction therefrom of the depreciation as observed by Mr. Biddison, and in which you ask me that if Mr. Hamilton had come in with a reproduction cost new estimate of $75,000,000 instead of $57,000,000 approximately, and a reproduction cost new less depreciation estimate of $70,000,00 instead of approximately $54,000,000, I will say that—if I had no opportunity to go into Mr. Hamilton's figures in detail and were asked to base my judgment on his reputation and on my general knowledge of his methods in respect to such properties as this, if he said that in his opinion the value of the physical property was the figure you named—this addition of mine should be made for going concern value. I think Mr. Hamilton is a competent man to testify for reproduction cost new in this type of proceeding.

Questions by the Examiner.

If a competent witness testified that the reproduction cost estimates would be $75,000,000 and less depreciation would be $70,000,000 and those figures applied to the physical property alone, I would still add $8,500,000. If the figure of reproduction cost should be $10,000,00 less depreciation of $15,000,000, leaving a reproduction cost figure less depreciation of $85,000,000, the grant total cost of attaching business might be different to the amount I have determined in that the depreciation might be different and if those amounts applied to the physical properties alone, I would still testify that the amount of $8,568,093, or a higher amount, should be added as an element of going concern value. It should be added to any authentic valuation of the physical property.

I will furnish counsel with a statement of the cases in which I have testified in the last 10 years.

Redirect Examination by Mr. Morgan.

If the same expense or cost had been paid out for interest, for soliciting customers, for taxes, for operating expenses, not dependent on volume, and the same depreciation had occurred annually as that set out in my Exhibit 130, then my judgment would be, without regard to the value of the physical property, that a going concern value allowance would have to be added to the value of the physical properties, whatever that value was found to be. In stating that I have considered all of these elements as adding to the going concern value and in stating that the going concern value should be at least $8,568,093, I mean that that is not all of the going concern value that I think exists here, but in arriving at that amount, I have confined it to that amount because I can only identify that amount as actual expenditures that occurred in connection with producing this property. My testimony has been that the going concern value is not less than the amount stated and not that it is that exact amount.

993 S. L. MILLER, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(September 6, 1939)

My name is S. LeRoy Miller. I am the chief accountant of Natural Gas Pipeline Company of America and of Texoma Natural Gas Company, under the supervision of Mr. Campbell I supervise the accounting.

I personally prepared those figures which I have heard revealed here by Mr. Em [illegible] and which appear on page 3, of Exhibit 130. I prepared those figures under the direction of Mr. Campbell and took them from the books and records of the company.

(EXHIBIT 130 was offered in evidence and was admitted over the objection of counsel for the Commissions to each of whom the Examiner granted an exception.)

994 R. J. WALLACE, a witness for defendants, testified as follows:

Direct Examination by Mr. Morgan.

(September 7, 1939)

My name is R. J. Wallace. I live in Tulsa, Oklahoma. I am in the oil and gas business and I conduct a brokerage business for the purchase of oil and gas properties.

I have been engaged in the oil and gas business either as a producer or as a broker since 1907. I have been actively engaged in the brokerage business as well as an operator for over 10 years. In 1907 I went to work in the oil fields at Bartlesville, Oklahoma, as a night pumper and roustabout. from 1908 to 1909 I was employed by the Prairie Oil and Gas Company in their civil engineering department on tank construction and pipeline construction. From 1909 to 1911 I attended college in the winter and in the summer worked at surveying and as a tool dresser, and in general oil field work. I secured some oil and gas leases for companies and individuals during that time. In 1912 I was electer registrar of deeds in Washington County, Oklahoma, the county seat being Bartlesville. In 1913 I resigned my position as registrar of deeds to accept the position as assistant superintendent of land and leasehold development of the Quapaw Gas Company and associated companies, which later became the Empire Companies. My work consisted of acquiring and supervising the taking of oil and gas leases by purchase and direct from the land owners in the states of Alabama, Mississippi, Arkansas, Louisiana, Texas, Oklahoma, Kansas, Colorado, and Wyoming. From 1915 until 1919 I was with the gas division of the Empire Companies and was made superintendent of gas pipelines in the Cushing district. In addition, I purchased all gas production properties and acquired gas leases for the gas division. From 1919 to 1920 I was manager of oil and gas operations in Louisiana for the joint account of the Empire Companies, the Barnsdall Oil Company, and H. V. Foster interests. My work consisted in drilling wells, purchasing leases and selling leases to help finance the project. From 1921 to 1924 I was located in Billings, Montana in charge of oil and gas operations for the Barnsdall-Foster Company, a corporation owned by the Barnsdall Oil Company and H. V. Foster interests, operating in the Rocky Mountain States. I leased direct from the fee owners and from the Government under Government permit, and supervised the drilling of wells and the sale of leases and production. In 1924 I sold a half interest in the properties of the Barnsdall-Foster Company to the Mid-West Refining Company, a subsidiary of the Standard Oil of Indiana, by which they took over the management of the properties. In 1925 I resigned from the Barnsdall-Foster Company and organized the Record Petroleum Company, a company in which I owned a substantial interest. In the latter part of that year I sold a half interest in the Record Petroleum Company to the Mid-West Refining Company and surrendered the management to them. I then engaged in the brokerage business and the business of a drilling contractor.

In 1926 and 1927 I secured leases and permits in various fields in Wyoming, Montana and New Mexico for my own account, and later sold these properties during the years
1927 and 1928. In 1928 I moved to Tulsa, Oklahoma
995 to engage more actively in the brokerage business and
in valuation work.

In 1929 I devoted practically the entire year to the consumating of two large transactions and to the investigation of other properties. From 1929 to 1932 I conducted a brokerage business, and also developed a gas property east of Kansas City, Missouri, in connection with which I drilled a number of wells and built a pipeline system. From 1932 to 1935 I conducted a brokerage business in Kansas, Oklahoma and Texas, and sold my gas wells and gathering system east of Kansas City. From 1935 to 1936, in addition to my brokerage business, I served as vice president and general manager of the Signal Oil Company, a producing company operating in Kansas and Oklahoma, in which I represented a bank of Tulsa. This company had become indebted to the bank which made it necessary that they place the management under its direction, and it asked me to act in that capacity.

In 1936, after drilling some additional wells, I sold the producing properties and some of the undeveloped leases for enough to pay the bank's indebtedness and turned the property back to its owners. From 1936 to 1938 I drilled a number of wells in Kansas—oil wells and gas wells—which resulted in the building of a gasoline plant on the properties. In the latter part of 1938 I sold my oil interests and have since been engaged entirely in the brokerage business.

The two or three transactions which occupied the entire year 1929, to which I have referred, involved first the sale of an undivided half interest in approximately 492,000 acres of undeveloped leases scattered through Kansas and Oklahoma, belonging to the Amerada Petroleum Corporation, to the Standard Oil Company of Indiana, and next a sale to the same company of the McMan Oil Company properties. This was a producing company which had both producing and undeveloped properties in Texas, Oklahoma and Kansas. The consideration for the purchase of the half interest of the Amerada Petroleum Company by the Standard of Indiana was $10,000,000. The consideration involved in the sale from McMan to the Standard, which was a stock merger, was approximately $12,000,000. (Objection by Commission Counsel to testimony relating to consideration for purchases overruled.) Both of these transactions involve properties, though not very extensive properties in the Texas Panhandle field. During that same year I was delegated to attempt to sell the Foster Petroleum Company. I took this property up with the Standard of Indiana but we did not consummate the transaction. My contract in this deal set out that the consideration would be somewhere between $10,000,000 and $20,000,000, that is to say that was the range of prices involved in the negotiations.

I think I have had occasion to become acquainted with and acquire knowledge of the market conditions in the Texas Panhandle field. I first became acquainted with that field at the very beginning of operations when I was employed by the Empire Companies, and I remember when the first well was drilled in there, and wells at later times. Under my supervision we acquired acreage, checkerboarded and scattered acreage in that country, in the early development of it, suspecting that there was a large producing area there. I have since acquainted myself, in the course of my business, with transactions that have taken place, and with the values in that field. I know the present boundaries of that field. It is a generally accepted proven area. By
the development that has taken place over these past
996 years it is now accepted as a proven field extending over
portions of Potter, Moore, Hutchinson, Carson, Gray, Wheeler Counties, and I think a small portion of Hartley County. I have kept myself advised concerning the market

conditions prevailing throughout that field over the past several years. The gas leases scattered over the now generally accepted area covered by this field as it is usually outlined on the map, are not of uniform value throughout the field. There are many conditions prevailing in that field and I would not say that they are of uniform value at all. I would say the range of values would be from nothing up. The reason I say that some leases in that field would have no value at all is that there are areas where tracts of land for lease purposes would be absolutely condemned and would have no value. Dry holes have been drilled out over the area that is commonly included in the boundaries of that field as it is mapped by the public authorities and by the people dealing in oil and gas activities in that field.

This field is a very large one—approximately 125 miles long—so we are speaking of a very large area. In the eastern part of the field the land is divided into what I would call small tracts, in the gas area, 160-acre and 320-acre tracts. In the area are Carson, Moore and Potter Counties there are very large tracts of land under one ownership, so the sizes of the leases vary from very small tracts to very large tracts. In Moore and Potter Counties the tracts are large, a great many of them, but there are a few small tracts. In Carson County there are some large tracts and some small tracts.

When I say I have been engaged in the brokerage business I mean that I buy and sell properties or negotiate for the purchase of properties for a particular client. I mean, of course, oil and gas properties and leases.

My business has been to bring the seller and purchaser together on sales transactions involving oil and gas properties. Beyond that I try to study the needs of some of my clients or companies. Because of that knowledge and because I keep up with the different fields, sometimes I have been able to analyze their needs and present to them desired property and make the sale of such property as a broker. I create my own business in that way, receiving my compensation as a commission on the sales price, or a finder's fee or a commission for negotiating the purchase.

The principal factors in valuing the property in the Texas Panhandle field would be first its location as to the generally accepted proven gas area. Another factor would be its location within the proven area, as to the potential producing area—whether it is in a highly productive area, because these areas change rapidly. You find areas probably within the center of the general producing area that, possibly on account of tight porosity, or something, are not within the high producing areas. The field has enough history at this time that we can very intelligently pick out those areas.

997 Another factor would be the conditions and terms of the leases under which the land is held, if it is a large reserve that you are looking over. In the history of almost all leasing, when a field becomes attractive or shows that it is a producing area, or might become a producing area, there is a great rush to secure leases; and almost invariably these leases are written at approximately the same time or within the same year. They are usually written for the same primary term, five years or ten years as the case may be, because when you give a proposition to one land owner it is almost universally the proposition that goes through the field. Therefore, the terms of the leases are very important. To illustrate, the dates of the leases being practically the same time, there would have to be a well drilled within the same period of time on each lease. A lease is really a franchise to produce oil or gas, and you have a right to drill and produce provided you do it within a stipulated time or the primary term of the lease. You do not have title to the oil or gas unless you actually produce it. From that time on you have as long as oil or gas is produced thereafter.

Another factor would be whether on a large reserve the acreage was well blocked. That is necessary for the reason that the offsetting or well spacing can be under the control of the owner or operator of this acreage, and can be done in a more uniform way. The withdrawals particularly of gas can be under the control of the operator and not subjected to close offsetting by others whose market might be entirely different from the operator or owner of the large block. There are other factors, the rock pressure and the decline in pressure. The field has enough history behind it so as to show its approximate decline and what you might reasonably expect to recover from the amount of gas or oil that you might estimate is under your land. I think those are most of the controlling factors.

Let us take, for the purpose of illustration, an ordinary oil and gas lease from A to B, covering a tract of 320 acres of land. Under the provisions of the prevailing oil and gas lease contracts as they were originally executed in the Panhandle, it is practically universal that that lease reads

that it is a conveyance of oil, gas, and other minerals for a definite period of 5 years or 10 years, or some other stated time that we call the primary term, and as long thereafter as oil or gas is produced from the premises. That provision is contained in practically every lease down there. Each lease also shows the amount paid for the lease. This is usually termed the original bonus. The payment of that bonus defers the drilling of a well for one year, after which, under further terms of the lease, the lessee is required to pay a delay rental for the privilege of deferring the drilling of a well for each additional year up to the end of the primary term of 5 years, if it be a 5-year lease. If at the end of the primary term the lessee has not drilled a well and is not producing oil or gas from the lease, the lease automatically becomes null and void. If a well be not started or the delay rental be not paid at the end of the first year the lease automatically terminates. I am familiar with what is known as the obligation to offset that goes with an oil and gas lease. If a well on the land next to the land on which you have the lease is close enough that your lease will suffer drainage, there is an implied covenant under the court decisions requiring you to drill a well equi-distant from the line of your lease as the well on the adjoining tract, so that the withdrawals from the two wells will
998 offset each other. This covenant arises by reason of
the fact that the land owner in most cases reserves one-eighth of the gross production of either oil or gas that is produced from the lease; that the paying and protection of that one-eighth interest is a part of the consideration for the lease. If drainage takes place the land owner loses a part of that one-eighth and therefore the holder of the lease is required to drill such an offset well to protect his royalty owner's interest as well as his own.

It is not necessary that the production from the well on the lease equal that from the well on the adjoining land. The obligation is fulfilled if a well be drilled at a similar distance. Of course you might find a very large well on the land adjoining yours and you might drill an offsetting well which would turn out to be much smaller due to the unexplainable conditions underground that we do not know about when we start the wells.

The obligation is to drill the well at the same distance from the common line as the well on the adjoining tract so as to protect against the gas being drained from the lease over to the other well. The number of offset requirements

is dependent upon the number of offsets drilled around the lease. It is possible, depending upon the form or the shape of the tract of land covered by the lease, for a lease to become heavily burdened with offset requirements in the absence of some special contract to protect against that sort of obligation. If the owner of the lease be able for a consideration to negotiate with the owner of the land or the owner of the royalty interest an agreement by which he absolves himself from an obligation to drill offset wells, and by which the land owner or royalty owner accepts one well on the tract as sufficient development with an express provision that no additional offset drilling will be required, such an agreement would add great value to the lease. The extent of the drilling operations is a matter of great interest to a prospective purchaser. It is one of the controlling factors of the buyer of leases as the drilling of a well involves the expenditure of many thousands of dollars. If the lease or group of leases requires the drilling of a great number of wells, or might require the drilling of a great number of wells, he would certainly not pay much for the lease. The amount he would be willing to pay for it is directly affected by the extent of the burden of development that goes with the lease he contemplates buying, because the operator or purchaser of the lease expects to make a profit and therefore does not want to put in too much of an investment which might go beyond what he would consider is possible if he is to make a profit from it. To illustrate, let us assume that in some neighborhood or vicinity there are four leases which have been acquired by the same owner on lands belonging to the same lessor or different lessors, as the case may be. Let us say that one of those leases covers 320 acres, another 200 acres, another 160 acres, and the other 80 acres. If the primary term be 5 years it will be necessary to drill a minimum of one well to each tract in order to continue the lease beyond the 5-year period. Otherwise the lease would terminate as to each tract on which a well was not drilled and put on production during the 5-year period. This is the minimum drilling obligation. If wells were drilled offsetting these tracts it would be necessary, in the absence of some agreement
999 to the contrary, to drill offsets to protect against each
well which the four wells to be drilled as a minimum happen not to offset.

(Mr. Morgan, counsel for defendants, made the following statement to the Examiner:

It is the obligation of the lessee to drill well for well in the case of offsetting wells, unless there is some special agreement to the contrary. The Texas law carries into the leases, although it is not written there in express words, what is termed an implied obligation to protect the royalty owner against having his oil or gas drained off to other wells. That requires the drilling of offset wells on the lease to protect it against that drainage. That subjects the owner of the lease to liability for the damage sustained by the royalty owner through that drainage, and in some instances the cancellation of the lease. That is not a matter of statutory law but of common law written into leases by the courts in passing upon the rights as between the royalty owner and the owner of the lease. If there should be two wells on adjoining property the owner of the lease might drill one well between them and thus protect the lease against drainage from both wells. However, it becomes an issue of fact under those circumstances. Down in Texas where we have juries in both equity and legal proceedings, there is always a jury's verdict on the facts staring the owner in the face when he takes a chance like that. That common law obligation obtains in other oil and gas states so far as I am advised. It certainly is in Texas a well established law throughout the state. The rule has been repeatedly announced by the Appellate Courts, including the Supreme Court of the state. I would not say that this obligation arises more or less frequently in the Panhandle than in other portions of the state.)

Direct Examination Resumed by Mr. Morgan.

You will find a rather uniform spacing of wells in all fields in Kansas, Oklahoma, and in other producing states. I think it has come about more by the getting together of the principal operators and establishing an offset distance. I can illustrate by a field in which I was operating in Kansas, the Burton field. In the north end of the field the leases were owned principally by one operator and he set the spacing at 40 acres per well. In the south end of the field where the owners of the leases were scattered, leases were divided up among a number of them, and the offset obligation became universal at 10 acres per well, and it did prevail at 10 acres throughout that almost entire southern area.

Questions by the Examiner.

In the Panhandle field the spacing varies. In speaking of oil wells, I think 10-acre spacing has been used up along the north boundary where the oil area is, but in the gas area, in the east end of the field, the density of drilling for gas is one well per 160 acres, and that holds true in some places in Gray and Carson Counties, but in Moore County and Potter County, where the land or leases are held in large tracts, they have apparently either agreed or, at any rate, are drilling one well to 640 acres. Now in all my experience in gas fields I have never known a place where 640 acres has been allocated to one well. It is the largest 1000 unit, I think, that I have ever experienced, but that seems to be the practice there. I do not believe there is any law in regard to that but it has become more or less universal there.

Direct Examination Resumed by Mr. Morgan.

That 640-acre unit may have to be reduced as necessity for additional wells develops through the decline in the field pressure. There is no question about that, in my opinion, because naturally when the pressure goes down the production will go down. This will require a great deal of additional drilling to keep up the delivery of gas from that area. I do not mean to say that in Wheeler County and in eastern Carson County, where the unit is usually 160 acres, that all the leases are drilled to that density. In many instances wells are drilled on 80-acre tracts; in other instances there are wells on 40-acre tracts, on 20-acre tracts, and even on 10-acre tracts.

Going back to the four leases we used in the illustration a little while ago, which we will call leases A, B, C, and D, which are all for the term of five years and in the same neighborhood either adjoining each other or close to each other, I have stated that it would require a minimum of four wells to retain the title to these oil and gas leases beyond the primary term. Until one well is drilled on each tract, it would be necessary, in order to keep the title to the oil and gas lease alive pending the termination of the primary term, to pay a rental at intervals of a year. This rental usually amounts to a dollar per acre. Now let us assume that the owner of those four leases makes a new agreement with the owner or owners of the royalty interests underlying those leases, by which, for a consideration, it is agreed that one well will be drilled on the four tracts at a location to be determined by the lease owner, or by agreement that from that well the proportion of the total market outlet of the owner, which is properly allocable to the total of the four tracts of land be produced from one well, and that no other well shall be required in order to keep the four leases alive, or the title to the oil and gas reserves under the leases alive beyond the primary term, and also that there shall be no further obligation to drill offset wells. Such an agreement would add great value to these leases for the reason that you first have just the cost of one well to drill. You may eventually drill on four tracts, but that would be to suit your market conditions. The point is that you then acquire title to the oil and gas lease. Before that your title depended on the development through the drilling of one well on each tract. It would therefore add great value, in my judgment, to the leases.

The owner, by such an agreement,, becomes the proprietor of this oil and gas reserve and it does not depend upon the drilling of additional wells by the end of a stipulated period of five years, or ten years, as the case may be, and the payment of a rental in the meantime, failing in which the title will absolutely terminate. The owner of the lease is no longer subjected to damage by offsetting wells and underground drainage. The elimination of this hazard, in my opinion, adds to the value. Such an agreement would certainly be looked on with favor by one who was contemplating the purchase of the reserves underlying those leases.

1001 I have been requested to make a study of the leases belonging to Texoma Natural Gas Company in the Panhandle field for the purpose of determining their value at the present time. I was first employed to make this study about April 1, 1938, at which time I commenced to make an investigation into the reserves of that company. I have continued this study at intervals from the date last mentioned to the present time. I have made a very careful study of the holdings of that company. I have been on or in very close proximity to each lease. I have been to each of the gas wells. I have spent many weeks in the office at Amarillo and in the field, and have gone into the records of the company. I have studied each lease individually as to its terms, its location, and all things, both favorable and unfavorable, that would go towards establishing, in my opinion, the value. I have taken into account the things that add to and the things that detract from the value of those leases under the existing conditions. I have renewed my study of the field, the history and age of Texoma's wells, the dates when they were drilled in, the original open flow and rock pressure and the latest official open flow and rock pressure. I have made a study of the wells surrounding the Texoma property on the lands owned by other companies in order to determine the potential productivity in the areas where Texoma's acreage is located. I have checked also the open flow and rock pressure in those areas, in fact I believe I have checked into most of the controlling factors. (Objection by counsel for the two Commissions overruled.)

I have been furnished with a description of all of Texoma's leases and have located those leases on the map at the time of or prior to my going on the leases themselves. I find the greatest majority, the largest percentage of Texoma's leases are located within the areas of higher potentials; that the leases are well blocked, under most favorable conditions to an operator; that the terms of the leases particularly are very favorable; that the drilling of wells to hold intact this reserve is a minimum, and to me it shows the result of a well-trained organization and a great deal of work to put this reserve in the favorable operating position that it has at this time.

By being well blocked I mean that the leases are substantially joined together or blocked together in one large block or in several blocks of large enough magnitude so that the operator or owner of those leases does have quite a control over the offsetting distances and he can protect his withdrawals from them.

The ownership map that has been offered in evidence shows that there are several or quite a number of tracts in northern Carson County that are comparatively small. I have in mind particularly those in what is known as the Burnett ranch referred to in the record. The fact that the company owns these smaller tracts ordinarily would raise a serious objection to the value of the lease for the reason as I have already stated, going to offsetting and drainage protection obligations. However, in this particular location it is generally accepted, and I feel a buyer of leases would accept it, as an area proven for gas only, because there ~~has not been any oil developed~~ in any of the wells. Gas

not be stored. It has to be produced from the wells as
market will absorb it. The fact that this acreage is surrounded
by the large reserves of other gas companies
whose withdrawals of gas are at a rate similar to that of
the Texoma Natural Gas Company, and whose markets
are controlled by weather conditions, industrial con-
1002 ditions, and other factors the same as the markets
of Texoma, in my opinion puts that acreage in as safe
position as if it were blocked acreage. I have therefore
considered that factor in my treatment of those smaller
tracts.

I find that the main body of Texoma's present reserves are so located as that they are readily accessible to a gathering system that would represent what in that field would be a minimum investment in gathering facilities in order to reach them. I have considered that factor. This field being as large as it is—of course the leases of Texoma from the west to the east end are many miles apart but the area over which they are scattered is a proven area and is so considered—the locations of the leases are very favorable for the construction of gathering lines, and their distances apart are not prohibitive from an investment standpoint, so from an operator's standpoint I find them well selected. There is a great advantage, providing the terms of the leases are favorable enough that the drilling of wells would not defeat you, in bringing together in one ownership a large number of leases, say several hundred, as of the time originally taken. Such an assembling of the acreage adds to the value over the aggregate sum of the values of the leases separately. This is particularly true in the Panhandle where the owner of a small lease is at the mercy of a local market which may be developed, a market that he did not himself create or control. Therefore, an isolated tract of 160 acres, or 320 acres, or even 640 acres owned individually would not have much value. It may be in a prolific area, it may be in the highest potential area, but still it would not be large enough to create its own outlet. Therefore, a large reserve or a number of leases under one ownership which could and would create an outlet to a distant market, has additional value over that of an isolated or individual tract. The owner of a large block of acreage can go out and seek, and probably find, an outlet which any one of these individual owners of small tracts would find absolutely out of the question. The reserves of Texoma are sufficient through the pipeline of

Texoma and Natural Gas Pipeline Company. They are of sufficient size, are located in proven areas, and would create an outlet to a distant market. In the case of Texoma I find agreements which have brought to its reserves the advantages pointed out in the illustration I discussed a little while ago. A great majority of Texoma's reserves are held under what they call consolidations. Through these consolidations they have brought about a grouping of their small leases or an understanding as to the development of their larger leases. Contracts have been executed between the land owners who won the royalties under the different leases and the company, consolidating under one contract or operating arrangement several leases under which agreement one well or two wells, as the case may be, will hold these leases in force as long as gas is produced from this one or these two wells. These contracts further provide that all of the leases within that consolidation are held in force even though they go beyond their primary term—and I find some leases that, under their original form, would have expired if it were not for these consolidations; that they will not be required to pay rentals to these land owners and are not required to drill offsetting wells. The owners of the land on which are the leases included in a particular consolidation agreement and on which wells have not been drilled, participate in the royalty from the well that has been drilled on some other tract whether he has any interest in the land on which the well was drilled or not.

1003 These contracts provide that the withdrawals of gas from that well shall be taken in proportion to the open flow and the acreage covered by the consolidation agreement as a whole, and the owner of a tract of land on which there may not be a well participates in the royalty in proportion to the ratio of his acreage to the whole. It certainly is a very very great advantage to an operator because he can defer the drilling of many wells until such time as his market requirements would justify the drilling of additional wells.

I find that of the 140,000 acres in Texoma's reserve there are over 98,000 acres that have been validated under these consolidation contracts. Now, the other acreage owned by Texoma, the larger part of it is held in large tracts like those of the Magnolia lease in Carson County and similar tracts. The Magnolia lease, for instance, covers 4,500 to 5,000 acres.

The record shows that no rentals will be payable on Texoma's acreage after the year 1940. That means that these leases will have all become validated or cured, to use an oil field expression, without the payment of further rentals, by reason of the fact that wells will have been drilled on the tracts covered by those leases or on leases covered by consolidation agreements. That circumstance adds to the market value of Texoma's lease reserves in the Panhandle. When I said that the owner of the consolidation obtains an added value under the consolidation agreement by reason of deferring drilling obligations, I mean that his contractual obligations to drill wells for the purpose of keeping the lease alive or to prevent its termination at the end of the primary term and the obligation to protect against offsets in the case of this more than 98,000 acres covered by these consolidations, have all been discharged and he will not have to drill any other wells unless he wants to drill them to meet the purposes of his business. The placing of several leases, like the four I used in the illustration, under one consolidation agreement changes the value of the aggregate of the four leases taken separately. In fact the individual leases have almost completely lost their orginal identity. You will find in the consolidations tracts as to which the leasehold estate is in full force and effect although the original lease or leases covering such tracts have long since expired by their original terms. If they were operating under their original lease agreements these leases would no longer be in effect.

(At this point counsel handed the reporter a document captioned "Market Value of Leases of Texoma Natural Gas Company by R. J. Wallace" with the request that it be marked as an exhibit for identification. At the direction of the Examiner the document was marked Exhibit 131 for identification.)

I have classified into separate groups or classifications the acreage owned by Texoma Natural Gas Company as of June 1, 1939. I found it necessary to classify the acreage or reserves of Texoma in several different classifications, for the reason that they are in several parts of the field where different conditions exist. I made a classification for all of the acreage as of the present date, but excluded leases which Texoma will cancel during the years 1939 and 1940. I asked for a list of the leases to be cancelled by the end of 1940 and received such a list from the management.

1004 I have grouped Texoma's reserves into eight classifications and have designated those classifications A-1, A-2, A-3, B-1, B-2, B-3, C, and Sour Gas acreage.

In classification A-1 I have included what, in my judgment, is the choicest or best acreage. In Class A-2 I included acreage which I found had some factors which did not classify it as being the highest type of acreage, and so on down in each class. The sour gas acreage is acreage which appears within what is generally accepted as the sour gas area as of the present time. The sour gas line, or line between the sour gas area and the sweet gas area, has been designated and is generally accepted by operators and buyers of leases as being there, although the production comes from one common source. For some unexplainable reason there is a sour gas line there and I have excluded the acreage on the sour gas side of this line.

In classifying this acreage I have weighed all of the elements entering into the value, those elements that add to the value and that detract from the value of these leases. I have classified them into these eight classifications as a result of the exercise of my best judgment as to which classification they fall under in the light of all the factors. I have taken each lease separately and studied it as to its location, as to potentials and rock pressures, terms, conditions as to the location to other acreage, and have made a notation in my exhibit on each lease of these points and have placed it in the classification under which, in my judgment, it would fall in the light of those factors.

I have not included in the valuation of a particular lease on which there is a well or several wells the value of the well itself and the equipment belonging to the wall. I merely used the well as an index to me as to the potential area in which the lease is located, or the production from the well as an index to what a particular lease owner might expect to recover from this land.

In the classification and valuation of these leases I have not considered them as a part of the pipeline system composed of defendants, and have placed no value on them as if they were connected to any pipeline. I have valued them as if they were not connected to the line of Texoma. My judgment is that if this reserve were available to be purchased by buyer that he could and would create an outlet to a distant market.

I have before me a copy of Exhibit 131 for identification. This exhibit was prepared by me and under my direction. I have set out in this exhibit the leases on which I have arrived at the fair market value as of the present time. I have taken each lease separately, shown the lease numbers as corresponding to the numbers of the books of Texoma, the date of the lease, the term of the lease, the book and page on which it was recorded, the name of the lessor, the county in which the lease is located, the number of acres, the description of the lands, and the number of wells, if any, on each lease, the date when the well was completed, its initial open flow and the rock pressure as set up on the records of Texoma.

I have also included the latest open flow and rock pressure observed on the books or records of the Texas
1005 Railroad Commission. I have shown the royalties
payable to the land owners under each lease and whether or not the lease is now producing. I have put on each sheet the numbers of the other leases that are included in this particular consolidation, and I have also noted by remarks as to the location of the acreage with regard to the potential area and as to whether or not it was a part of a consolidation. I have marked on each lease my opinion as to its classification and value. I have placed in this exhibit one of these consolidation agreements of which I have testified as an illustration of what I am talking about. This copy I selected because it is a representative form of contract. Following that, I have briefed each consolidation, giving the county in which it is located, the number of the consolidation as set up on the books of Texoma, the name of the consolidation, the date, the total acreage, the number of leases included in the consolidation, and the lease number of each of those leases and the description of the lands. I have also made a notation as to the number of wells of which this consolidation agreement defers the drilling, by which I mean the number of wells that would have had to be drilled under the terms of the leases affected by the consolidation and which the owner is no longer obligated to drill.

This typical consolidation agreement appears between the tabs marked "Consolidations" and "Moore County." It is an agreement between W. H. Taylor and Texoma

Natural Gas Company. Under its terms, four leases originally executed by this lessor and finally acquired by Texoma were consolidated into one development unit. The first lease was dated April 14, 1926 and covered 608 acres; another dated April 19, 1926 covered 320 acres; the third dated August 16, 1929 contained 209 acres, and the fourth dated April 19, 1926 contained 125 acres in one tract and 160 acres in another tract. While there were four leases affected by the consolidation these four leases in fact embraced seven different tracts of land as of the time Texoma acquired it. That is, they came to Texoma under seven different assignments. That was due to the fact that the land covered by the original lease had been subdivided and a part of it assigned to one owner and a part to another before these leases were finally acquired by Texoma. By the terms of paragraph 2 of this consolidation agreement no further delay rentals were required to be paid on the whole 1,422 acres after the drilling of the first well. Over on the next page, in paragraph 6, we find this provision:

"There shall be no obligation on Texoma to drill offsets to any gas well which may be drilled on or produce gas from neighboring lands; but Texoma may drill additional wells, if, as and when it so desires."

That is the provision about which I was talking when I referred to the advantage and the added value to the reserve covered by one of these consolidations over the aggregate sums of the values of the separate leases not so consolidated. In the record is an exhibit numbered 68 from which I show the Examiner the location of the lands covered by that consolidation agreement. First is the lease of all of section 21 belonging to J. B. Wheatley in Moore County. This is located at the place to which I am pointing on the map. It is a long tract of land, the description of which I have just stated. Right down in that section, in the area colored red below the letters "O." and "R." in the spelling of "Moore" County appears this 608-acre tract. The second tract is the E/2 of Section 19, Block M-1, Moore County, containing 320 acres. This tract adjoins the 608-acre tract. It is immediately south of the east end of the first tract. The
1006 next tract is the west 82.3 acres of Section 18. It is the tract immediately adjoining the first one on the northeast corner and is a long narrow tract. Next

is the north 126.7 acres of the west 251.7 acres of Section 17, a tract which adjoins the first tract on the extreme east, running north and south, and is a very long narrow strip. The land covered by this lease is 126.7 acres at the north end of this narrow strip. The fourth lease covers the south 125 acres of the west 251.7 acres of Section 17 and is the south portion of the same tract off of which the north 126.7 acres above mentioned is cut. And in that lease, quite far removed, a mile or more away, is the NE/4 of Section 20, Block M-1, in Moore County, which is a small square located at the place to which I am now pointing.

As a result of that consolidation agreement those tracts have been brought together in this irregular shaped form here, under one consolidation, with the provision that Texoma shall not be required to drill but one well on the whole 1,422 acres, and that no offsets would be required. If that were in separate leases it would be a very dangerously shaped lease because there are so many boundaries exposed for offsets. A purchaser, in viewing that lease, would take that circumstance into account, and he would place a higher value on it because of its having been brought under a consolidation than he would if it were still under the four leases separately.

A while ago I spoke of the Magnolia fee land which is all under one lease. I could indicate it approximately on this map, but if you wish a description I will have to check that from the records. It is in Block 4 of the I&GN RR Co. Survey in Carson County. It is in the part of the west side of this larger block shown on Exhibit 68, at the place I am here indicating. It is colored in red on this map.

I will now go through the exhibit and explain it briefly. The first article in the exhibit is an introductory statement in which I have included a description of the field itself, its location, approximate number of acres considered to be proven sweet gas acreage, and a general statement as to the location of the Texoma leases. Reference is made in this introduction to the development of conservation measures in connection with the operations of stripping plants through which for several years the gas was being exhausted at a rapid rate and wasted to the air. Reference is also made to some of the factors which

I have considered in arriving at my judgment as to the value of the leases.

The next subdivision is under the tab called "Summary" in which I have taken the leases of the Texoma Natural Gas Company and classified them as to developed leases and undeveloped leases for each county, showing the total acreage under each classification and the total value of the acreage under each classification. I have also shown the total acreage by counties and the total value by counties. This is followed by a recapitulation showing the total number of acres under each classification and the value thereof. I arrive at a total valuation of $13,288,552.10. This appears in the summary of the details shown in the exhibit.

I have also included an index alphabetically of the leases by counties. This index shows the name of each lessee, with the lease numbers that will correspond with
each sheet in each county. The lease number is
1007 indicated over on the last column on the right-hand
side of the index page.

Coming back to my summary sheet, it will be noted that I have classified under the classification A-1 in Moore County 30,931.86 acres. In my opinion, the market value of that acreage at the present time is $3,866,482.50. This is an average of $125 per acre. This is the average value which I have placed on all of the A-1 acreage under my classification of these reserves. I have found A-1 acreage in Moore and Carson Counties. In Carson County I placed under this classification 24,195 acres which, in my opinion, has a value of $3,033,375.

After weighing the various factors, I have classified some of this acreage as Class A-2 for reasons already stated. In the light of those factors it is my judgment that this A-2 acreage has a value of $100 per acre. The Class A-3 acreage, in my judgment, has a value of $75 per acre. The Class B-1 acreage has a value of $50 an acre, the Class B-2 acreage has different values ranging from $20 to $35 per acre. Some is valued at $20, some at $25 and some at $35 an acre. The acreage valued at these three different prices of acreage classified under B-2 is shown by individual leases. On acreage classified as B-3, I place a valuation of $15 as to a part of it and $10 as to the other. The explanation is found in connection with the discussion of the particular lease. On the acreage classified as C-1 I have placed a valuation of $10 or less per acre. I have given no value to the sour gas acreage for the reason that although it has a value for certain purposes, entirely different factors and conditions govern as to the valuation of that acreage and I have not made a study of those factors in the sour gas area. I have given no value to any acreage not a part of the sweet gas reserve.

In each of these classifications and in each of these valuations I have weighed all of the factors that I have stated here, and exercised my very best judgment as to the classification on which each tract or each lease or consolidation of leases would fall. In my opinion this sum of $13,288,552.10 to which these valuations add up is the reasonable market value of these leases at the present time.

Cross-Examination by Mr. Slaff.

There may be an arithmetical error in making up the total valuation placed on the A-2 acreage in Moore County. I can recheck that but I will have to go through most of the leases in order to do so. I applied the $100 an acre to each lease when I classified it and then totaled each lease. These errors, if any, I feel quite certain are attributable to the fact that some of the acreage figured out in fractions and I may not have taken into account the fractions of acres. My regular work sheets are not with me. I will check the matter during the noon hour.

I testified in the rate case before the Kansas Corporation Commission in July, 1931. The Cities Service Company was involved in that case. Also before the Illinois Commerce Commission in July, 1932 for the Peoples Gas Light & Coke Companay. In January, 1935 I testified before the Kansas Corporation Commission for the Cities Service Company. I believe this summarizes all the rate cases in which I have testified. In all these cases I was testifying on the valuation of leases.

1008 *Cross-Examination by Mr. Booth.*

I have made no studies of the life of the reserves in the Panhandle field in connection with my work on these valuations. At no time in connection with my work have I made any studies of the life of the reserves. As to whether I consider the life of the reserves a factor in determining the value of the leases, I consider the producing history of the well, which does indicate to me something of its life, but I would not venture to deal with the lives of the reserves. I am not an engineer.

The life of the reserves is a factor that would be considered, I think, by the purchaser of leases. He would have his engineers make up an estimate of their judgment of the life of the reserves. However, I do find that in cases where you have on a property a well which was drilled several years ago, and which has been producing for several years, and its original flow and rock pressure indicated a certain amount, and at this time it would show a small decrease in rock pressure or open flow, it would indicate or give you some idea of the life; but I could not venture to say how long it would produce or how much gas it would produce in cubic feet.

I think that is a factor which a prospective purchaser of leaseholds would consider in determining the price he might pay for the leaseholds. I do not believe that the total amount of natural gas in the field would affect the market value of the lease. It might affect the percentage of earnings that the owner might expect to make if he were delivering that to a market at a price. The price condition would have to be in there. You have to have a price for the gas recoverable from the reserves per acre; you have to establish that. I think the extent of the reserves does affect the price. I did not calculate the amount of recoverable gas per acre when arriving at my valuation. I did not give any consideration to that item because I do not know the amount of recoverable gas. I could not say that all of the factors which I considered were stated by me in response to questions directed to me this morning by Mr. Morgan. I believe that I know pretty well the minds of the sellers of leases and the minds of the purchasers of the leases. I have been in constant contact with them for a number of years and have taken into consideration those conditions that I feel, from my experience, that I know something about. You cannot break it down into dollars per acre, but I have considered those things along with the entire work that I have been doing.

In response to questions by Mr. Morgan I indicated some of the factors which influenced the market value of leaseholds. Those are the factors which I considered in arriving at the market value of these leaseholds shown in Exhibit

131. There were probably other factors which I did not enumerate. There are things that you see but I cannot just explain what they are from an operator's standpoint which put one lease in a little better favor than another—accessibility and so forth. There are factors that I considered other than those that we have put in. I do not know that I could name or explain just each one. I believe lease for lease I can pretty well do that, generally.

I think I stated the main factors. I do not recall any other factors at this time, but if we will go through this lease by lease I may find that I have made notations of other factors that I considered. I do not recall all of the factors that I named in response to questions by Mr.
1009 Morgan. You might have that read to me. Every
factor I named did have a great bearing on the proper placing of this acreage in the classification to which I assigned it and on its value. As I recall most of the important factors were brought out. I cannot say now that they were all brought out. I am afraid I will have to have those factors before I can answer your question as to whether or not I have named all the factors I considered. I will state that some of the factors that I had to use in arriving at my conclusions reflected in Exhibit 131 were the conditions of each lease as to its terms and the acreage contained therein; those leases that had wells on them, the conditions and the producing history of them, each well, from the time they were drilled in up to the present time. I had the history of each and every well and considered that as a factor.

The acerage as being blocked in with the other acreage owned by the Texoma Natural Gas Company, the consolidations of which I spoke and on which I spent a great deal of time, I considered very important factors. The accessibility of the acreage generally was another factor. I mean that although it covers a large area in miles from the west to the east, yet it is so located that it is readily accessible to the gathering system that might be built to market the gas. I considered also the potential of the area in which the acerage is located and indicated by the wells drilled not only on the leases of Texoma but other lands. I have a record of every well in the field within these areas showing the open flow and rock pressure, and the amount of gas marketed from every well as well as the amount of gas in cubic feet marketed from the wells of Texoma. By the potential area I mean the productivity of the area as indicated by the wells drilled within that area. This is an important element in the minds of the seller and the buyer. I think the factors I have named are the principal factors that I considered in there.

There probably would be other elements that would enter the mind of the buyer and which he might consider of importance, but I think the things I have mentioned would enter into his mind. Those are the things that you would have to know in determining the market value of the leases of Texoma. I know that the purchaser would consider these factors and he might consider others, but I do not know what they would be. These are the factors which I consider to be most important. I do not think of other important factors at this time. I do not think that I know what would enter into the mind of the prospective purchaser other than those factors which I have mentioned. There probably would be others.

Redirect Examination by Mr. Morgan.

I have studied the production history of each well and acquainted myself concerning the quality of gas which has been produced from each well, the rate at which each well would be capable of producing gas, and the rate at which it is producing gas at the present time. It is also true that a prospective purchaser of oil and gas properties frequently has engineering studies made of the potentialities of the leases under consideration. It is not always true, but engineering estimates of the recoverable amount of gas or oil are quite often made by prospective purchasers from the indications derived from the history of these wells and adjoining wells.

1010 *Questions by the Examiner.*

I have indicated the value of an acre, as I say, from my knowledge and my opinion of the minds of the seller and the buyer. There is no question but what several of the Class A-2 or A-3 or B-1 leases will probably develop to be as valuable as that Class A-1 acreage and that some A-1 acreage will not be as valuable as I have indicated. But the law of averages, I am quite certain, will prevail and the buyer of leases under this classification would feel secure that the law of averages would prevail.

In arriving at the $125 per acre basis for Class A-1 acreage I had to take into consideration several conditions there. I first took into consideration and allowed to it the density of drilling, 320 acres per well. In the east part of the territory 160 acres is used while in the west 640 acres is used, but I have never known of another field where as much as 640 acres per well was used. Therefore, I have allocated, and I think a buyer of leases would, 320 acres per well.

I also found from my investigation that the average field price for gas, a fair average field price, would be 4 cents per thousand cubic feet on a 16.4 pound basis. That is recited in a number of leases which I have read and in division orders of this company and other companies which I have read. If a buyer should pay $125 an acre and drill a well thereon costing him approximately $20,000, which I find is a fair average in the field, at 4 cents a thousand, he would pay the one-eighth or one-half cent per thousand to the land owner, and I have allowed 1 cent per thousand for operations, which is very high. The lease would have to produce approximately 7,500,000 cubic feet per acre to amortize the purchase price and the cost of drilling the well and producing it. This field, to my knowledge, has a proven producing area. The dry hole factor has been eliminated and it does not, in my judgment, seem to be a large amount per acre to produce to amortize the investment, and the buyer of the lease would consider that he could amortize that investment at that price and yet make a fair and reasonable profit. That was my approach to the $125 value.

Redirect Examination Resumed by Mr. Morgan.

In arriving at my judgment of the price per acre to allocate to the choicest or A-1 classification, I have made a study of the withdrawals and the amount of gas produced from the acreage that was owned by the several companies who market gas through pipelines. I went to the office of the Railroad Commission and from their books I took the total amount of withdrawals from all the wells of Texoma Natural Gas Company. That information I also had from the companies' records and the records of Canadian River Gas Company, Cities Service Gas Company, some of the properties of Hagy, Harrington & Marsh, and the records of the Huber Corporation, the Northern Natural Gas Com-

pany, the Panhandle Eastern Pipe Line Company, the Shamrock Oil & Gas Company, and the Red River Gas Company. I took those wells of the companies that were connected to pipelines under purchase contracts and took the total withdrawals of gas that had been produced up to November, 1938, which was the date I ascertained this. Not knowing the operating expenses of the many companies here, I used for my problem the allocation of 320 acres per well as the drilling density, and at 4 cents a thousand, which I had satisfied myself was the average field price, I figured out the amount of gas in dollars per acre that had been produced, the gross amount for each company. The overall or weighted average, considering the total number of wells of all of these companies, the total withdrawals, 320 acres per well, gave me an amount of
1011 $334.42 per acre that had been produced from these wells connected to gas pipelines. That gave me some indication of what the capability of earnings of this property was, and with my general knowledge of the field from a good many years of watching it, discussing it with engineers, operators, and heads of companies, in my judgment I am satisfied that there is still over 50 per cent of the reserves yet to be produced.

In addition to that, I knew of some transactions in the early history of the field in southwestern Hutchinson County of some acreage that was sold for more than $125 an acre, at a time when we did not know the producing history of the field. Taking all these things into consideration I placed a price of $125 an acre on my very choicest locations. From that point on, in classifying the acreage as to the many factors that I have explained, to that acreage which falls in Class A-1 I allocated $125 an acre. In other words, I tried to take an overall picture of the whole field for my judgment and not one particular tract at a time.

Questions by the Examiner.

I know that the $334 and some cents is the gross figure. I did not know the operating expenses of the different companies, the large organizations, and things of that kind. It would no doubt cost different prices per acre, but from my experience as an operator I felt that $125 was an acceptable value there. It has already produced a gross of $334 an acre as an average over all the wells connected to the pipeline, and I felt that $125 per acre was a safe value, a good, reasonable price, knowing in my judgment, and from my investigation, that there is well over 50 per cent of the production yet to be recovered. That is customary, I might say, in purchasing acreage. A company will pick out a certain area that they wish to go into. They will allocate a price, $50 an acre for this area, $25 for another, $15 for another. They do not pick out certain tracts within that area. It is a figure which they figure the law of averages will maintain in there. It is very customary among buyers of leases, in my judgment, to do that.

Redirect Examination Resumed by Mr. Morgan.

The weighted average of all these companies' wells connected to gas pipelines of which I could find the record in the Railroad Commission office, using 320 acres to the well and 4 cents a thousand as a field price, showed they had actually produced a gross of $334.42 per acre, on an average. I took as my judgment figure of what a purchaser would consider the choicest of the acreage to be worth, very substantially less than half of what the average production had been, based on that kind of a unit. A purchaser of acreage would unquestionably want to know what has been the average over the entire field, instead of the particular acreage he is considering buying.

Recross Examination by Mr. Slaff.

If I understand your question correctly as to anticipated production, I am quite certain that this field is recognized as a proven field. The dry hole hazard is eliminated and would be from the mind of the buyer of leases. I do not believe I have in mind specific ratios showing the relativity between price or value and production or anticipated production as expressed in dollars. I may be low on that price. I do not know. But I do feel, from my judgment and experience, that I have set a price as to which a buyer would consider that there is over 50 per cent yet to produce and he could pay charges and still realize a nice profit. There is no significance in the way Judge Morgan's question was phrased, that the price I set on this choicest acreage was half or less than half of the production in dollars today; I did not take a ratio of the weighted average at all on that.

1012 **K. V. ZWIENER**, a witness for defendants, testified:

Direct Examination by Mr. Hedrick.

(September 7, 1939.)

My name is K. V. Zwiener. I live at Evanston, Illinois. I was graduated from the University of California at Berkeley in the School of Commerce, majoring in economics. I am assistant cashier of the Harris Trust & Savings Bank, Chicago. This bank has total resources of approximately $285,000,000. I have been with that institution a little over ten years. Early in 1929 I went to the bank in the investment department. Prior to the enactment of the Banking Act in 1933 we maintained a bond department with representatives throughout the country, and I went into that division and represented the bank on the Pacific Coast. Subsequently the department was disbanded because the distribution of corporate securities was no longer permitted under the Banking Act; so I transferred back to Chicago and continued working with the securities division in connection with the purchase of bonds for our own portfolio and in connection with the servicing of accounts that we handled for individuals and corporations. I also made special surveys of investments for use in the handling of trust funds. Of course, we do not actually handle corporation securities any more except on order, but I am practically in daily contact with the markets for all types of bonds. My present work is primarily in one of the loaning divisions working on term credits. That, of course, means that we have to be watching the comparable return that the companies would get in the open market, and we are watching them constantly. I also consult with and work with the bank investment committee which does the purchasing of bonds for our own portfolio.

Our bank has a trust department which handles funds of various clients in a fiduciary capacity.

Of course, we all recognize that there is no security which is absolutely "risk-free." To me, and I think generally, the term "risk-free securities" has meant securities on which we feel sure we will have our principal paid at maturity and the interest will be paid as it become due and payable. To state it differently, they are securities which are closest to being absolutely risk-free that are available.

I believe the United States Government securities, that is, United States Treasury notes and bonds, direct obligations of the United States, are considered to be as close to being risk-free investments as we have available in the market today. I think you can so classify the high grade municipal obligations, that is the direct obligations of states, counties, cities, and other municipal divisions that have a high credit rating. By those having a high credit rating I mean those in which the relationship of debt to assessed valuation is relatively small and that have the support of unlimited taxation. I think such securities are pretty generally
1013 classified as risk-free investments. Bonds of this type are those of the State of Illinois, the State of Missouri, and the State of New York. I do not think you would classify many of our large cities in that group, at least none of them that I know of offhand.

If our bank as trustee were requested by a client or customer to invest a sum of money, say $3,000,000 or $4,000,000, in risk-free securities or the best type of securities available, with the greatest degree of certainty of a return of the principal at its stated maturity, and the payment of interest as it accrues, I think under such instructions I would be limited almost entirely to United States Government or municipal bonds. I do not think there are enough other securities which would meet the qualifications, that is, if there is any limitation on the maturity factors. For the most part, corporate bonds are very long maturities these days, and the yield obtainable does not compare favorably with United States Government or municipal bonds.

Under present conditions it has not been possible to accumulate any sizable block of high grade municipal bonds of relatively short maturities at any one time. It has usually taken a period of time to accumulate these securities. Governments you can obtain on practically any one day and buy a sizable amount. That is, there is always a very substantial amount of trading on Governments between dealers on the New York Stock Exchange daily.

(Company Counsel states purpose of testimony to show what rate of return or what yield an investor would have on investments under the sinking fund theory of amortization.)

The maturity date of a Government bond, of course, is the fixed date on which the principal becomes due and payable. All of the Treasury notes are issued with fixed maturities at a specified date: March 15, June 15, December 15, 1939 or 1940, whichever year you use. In the bonds you have not only your fixed maturity, but the Government has reserved the option to prepay these securities on a specified date. Such date is designated the optional call date. The optional call date would be the date on which the bond can be called for payment at par and accrued interest. The fixed maturity date is the date that the Government actually has the obligation to make the payment of the principal in full.

In the handling of a fund for a corporation of this character, such as Natural Gas Pipeline Company of America, since the fund has to be liquidated on a specified date, we would not buy bonds which have a fixed maturity extending beyond the date on which the fund would have to be liquidated even though the optional date came before the date of liquidation. Under the instructions you have outlined the fund must be returned or liquidated on a specified date. Operating as a trustee, or in a fiduciary capacity, we would not feel that we were at liberty to invest in bonds that matured beyond the specified date indicated, and we would therefore limit the maturity, that is the actual maturity date, within the liquidation date of the fund. It is readily apparent that we would be taking a risk of market fluctuations in any securities if we had a maturity later than that specified liquidation date. In other words, if the fund which the bank had accumulated as a trustee had to be liquidated on December 31, 1954, we would buy securities having a maturity date prior to that time.

1014 I have made a study of the yields of bonds that would meet the specifications I have stated, which would include only United States Government bonds and certain high grade municipal bonds. I was asked by the management of these companies to make such a study. This request came on August 15, 1939, and I made the study immediately after that time. I used the closing market prices as of the date last mentioned in that study.

If we assume that we have a fund of, say $4,000,000, which would have to be invested on the first of January, 1940, and a similar fund to be invested annually thereafter, and all of these funds had to be liquidated and returned to the company by the end of 1954; and if we take into account the market prices as of the date stated, August 15, 1939, for such securities as would be available for that purpose under the statement I have made, the yield to the investor, according to my calculation on Government bonds existing as of August 15, 1939, would be approximately 1.52%. That would mean that the first year we would invest $3,000,000 or $4,000,000 in a 15-year maturity. Using the prices prevailing on that date as a guide, I have taken the corresponding yields as though we were investing the fund for the whole 15-year period as of that date. Answering your question whether 1.52% would be the net yield that the investor would secure, there would be a trustee's fee, of course, for certain expenses involved in the handling of an account of that type, and there would be a charge for handling. Using the usual schedule of fees on a sizable fund, around .17% should cover these charges. That is the yield on the bonds using the call date and maturity, depending upon the coupon rate as a guide of what you might obtain for each one of these individual years.

I have given a little consideration to the fact that there are no Government bonds actually available today that meet the exact date of December 31, 1954, for example. There is not a bond that comes due exactly on that date, so I have added in a little higher yield in some instances because we do not know from this point on what type of government securities will be outstanding. The markets as of August 15, 1939, serve only as a guide.

(At this point counsel handed the reporter for identification a document entitled "Quotations and Yields of United States of America Treasury Notes and Bonds at Close of Market on August 15, 1939." At the direction of the Examiner, such document was marked Exhibit 132 for identification.)

I have a copy of Exhibit 132 for identification in my hands. I prepared that exhibit and will explain what it is and what it contains. The first column is the coupon rate of the various securities listed. The next column gives the maturity date of these securities. The next column gives the optional call date of these securities on which the Government has reserved the right to prepay. Under the column "Optional Call Date" there is no date indicated for "United States Treasury Notes." The reason for that is that the Government has not issued these notes with the optional feature. They are a short term security bearing a very low coupon rate. There is little or no chance of refinancing those because of the shortness of the maturity.

The next two columns of "Quotations" give the bid
1015 and offered prices as of the closing date indicated.

The next two columns show the yield in per cent. The first one would be with respect to the call date, if the issues were callable, and the next column gives the yield to maturity based on the fixed maturity of the notes and bonds. The last column indicates the amount of the issue outstanding in the hands of the public. It is noted that there are very substantial amounts of each maturity outstanding, which gives an idea of the opportunity we would have for purchasing those on any one date.

For example, take the issue of 3¼ bonds due October 15, 1945. This is the fifth item from the top under "United States Treasury Bonds." There is one billion four hundred million dollars of those outstanding in the hands of the public. At the top of the column on the extreme right-hand side there is no amount outstanding for the reason that the bonds there listed were due on September 15, 1939, and payment of those has already been provided for.

Questions by the Examiner.

Take the second item there, 1⅜ due December 15, 1939. They are quoted at 101-10/32 to 101-12/32, which is a negative yield. You do not get any yield on those bonds. If they were selling at par, 100.450, there would be just a zero yield to the maturity date. That comes about in most of the short term securities for a sort of a right value attached to them, because the Government has offered exchanges and the holders of these notes expect to get a new note that will immediately go to a premium that will offset the premium on these. On this particular day the first four maturities on the notes were actually on the negative yield basis. We had to go down to March 15, 1941, before we got to a zero basis and to June of 1941 before we could get a positive yield of any kind.

Direct Examination Resumed by Mr. Hedrick.

(At this point counsel handed the reporter a document entitled "Average Yield Obtainable from Investments in United States Government Notes and Bonds." Such document at the direction of the Examiner was marked Exhibit 133 for identification.)

I have prepared Exhibit 133 for identification, which is a tabulation showing the average yield obtainable from investments in United States Government bonds and notes during the next 15 years, based on the prices of those bonds and notes as of August 15, 1939. I have a copy of that exhibit before me.. This is an attempt to show about what the yield would be on the fund if you invested a certain amount, say, for example, on January 1, 1940, calling that the first year, and the nearest maturity that you could possibly get would be the June, 1954 range, and so on down. The second year you would invest for 14 years, the third year you would invest for 13 years, and the indicated yields in the Government's' outstanding today were used as a guide for obtaining an average yield. The description there is the coupon rate in per cent.

The coupon rate in per cent and maturity date and optional call date, the asked price, the yield in per cent of those particular bonds are shown in connection with the bonds outstanding and listed in Exhibit 132 for Identification.

I selected the particular bonds listed on Exhibit 133 because they come about as close to the maturity as we would want in a fund where the liquidation date is specified 1016 to be December 31, 1954. I, of course, selected bonds with a maturity prior to that date, and these particular bonds here listed have maturities closest to the date December 31, 1954 of any bonds obtainable.

The third column shows the maturity date of the notes of bonds, and the fourth column shows the optional call date. It just happens that the bonds I selected for those years to use as a guide were not optional bonds. As a matter of fact, they give a better indication of yield over a period of time than optional bonds because we are not dealing with the unknown factor of whether the Government will take them away from the owner on the optional date. Of course, treasury notes, which are used from the eleventh year on are non-optional bonds, also, or non-optional notes. If the Government should take any of these bonds away from the owner at a call date prior to the maturity date, we would have the fund on our hands and would have to reinvest it. In that case we would have to invest in other Government bonds of a shorter maturity, with the result that the yield under the conditions that prevailed on August 15, 1939, would be decreased.

I am not attempting to predict what the interest rates or the yields on investments will be over the period of fifteen years. In the fifth column in Exhibit 133 appears the asked price. I used the asked price instead of the paid price because the asked price is the price which the investor has to pay for any security, and the yield is figured on that price. Unless you are in the seller's market it is very seldom that you buy Governments on the bid side of the market. The only indication we have of what we can actually buy them for is the price asked. The second and third columns from the right-hand side under the heading "Yield — %" shows respectively the yield to the call date of the bond and the yield to the maturity date of the bond.

In a general market as it existed on August 15 the yield to maturity on that first issue is about 2.05%. That is about in line with my judgment of what a 15-year obligation of the Government with a low coupon would return at that time. I mean it did not appear likely that a 2¾ per cent bond would be refinanced, so we gave the weight to the maturity factor, although you are not sure even in that instance that you will get 2.05% because the possibility is that it may be called, in which event it would allow only 1.92%.

In the first group of bonds which would be purchased in the first year, of course, the maturity would run down almost to the date of liquidation, and we would have a yield on that particular sum of money invested almost to the liquidation date on the entire fund. The last column gives consideration to the fact that we do not have actual maturities to fit right on December 31, 1954, and if they were noncallable bonds of a fixed maturity right straight through the 15-year period, this, in my judgment, is about the yield that would be obtainable on this type of security.

This 1.52% yield is not just an arithmetical average. We have given consideration to the fact that the first year we have the fund invested for a 15-year period at 2.05%, and therefore you have got to give it a greater weight by 15. The yield of 1.95% on the bonds bought the following year would have to be weighted by 14, and so on. As a result the average yield is pulled up above the arithmetical
1017 average. Therefore, this 1.52% is the weighted average, giving consideration to the fact that the funds are invested in a higher yield of security for over a longer period of time than in the low yield securities. For example, if you had a $4,000,000 fund invested at the beginning of the fourteenth year, you would only receive a return of about .07%, and this schedule weights that in accordance with the 15-year schedule. The longer term bonds have a higher yield to maturity, and the short term bonds, such as those running for only one year, for instance, have a much less yield.

Questions by Examiner.

If, for instance, the fourteenth year began on August 15, 1939, I would have selected that issue on next to the last line for investment. The schedule is based on conditions as of 1939. The relation between Exhibits 132 and 133 is that Exhibit 132 gives all of the issues that are available for investment, that is, all the Governments that are outstanding, including both notes and Treasury bonds, and Exhibit 133 is a selection from those shown in Exhibit 132.

Direct Examination Resumed by Mr. Hedrick.

That is a selection I made of securities having a maturity closest to the date of December 31, 1954 or reflecting about the average yield for a specific period. For example, there in the ninth and tenth years I have used the December 15, 1945, maturity, the 2½ at 1945 in both cases giving the ninth year a yield of about .10 of one per cent better than the yield in the tenth year. That would be about the usual spread at that period.

No investment in the fifteenth year is shown. The reason for that is that there are no Treasury notes available today on which you can obtain a positive yield for a one-year period.

This .17 of one per cent opposite the line "Less Cost of Administration" is the bank trustee's charge, to which I referred, and the subtraction of that amount from 1.52% of course gives the net average yield to the investor.

The reason we could not go out on the stock exchange or over the counter and buy most any kind of a bond for an investment of this character is because we have more of a credit risk in most any type of corporate bond. When you go out in that field it is necessary to be very selective in obtaining the type of security that could be used in a trust fund account. Many issues of bonds outstanding have a high ratio of debt to property or earnings. It might be in an industry where your earnings fluctuate widely that circumstances would necessitate reorganization. Under such conditions we cannot be sure of the payment of the principal or interest as it accrues.

In other words, if this company wanted to invest funds so that it may have some kind of earning and at least get its principal back without fail, the only way to accomplish that purpose would be to invest in these risk-free securities which you say are United States Government bonds and municipal bonds.

1018 *Direct Examination by Mr. Morgan.*

I used the term "$4,000,000 on the first of January" for the purpose of arriving at a basis for my testimony. My testimony would be the same if the amount to be invested varied from $4,000,000 by $1,000,000 more or $1,000,000 less, or if any other date in the year were involved instead of the first of January. I used that figure because we were talking about a substantial amount.

Cross-Examination by Mr. Booth.

I did not say that one of the duties of my position is to advise the bank as to how it shall invest its own money. The policy with regard to investments is not handled by any one man in the bank. It is handled by a bank investment committee. I am not a member of that bank investment committee, but I consult with them in the purchase of securities for the bank's portfolio.

(Colloquy between Counsel and Examiner with respect to question asked by Counsel for Illinois Commerce Commission.)

Questions by the Examiner.

I have never advised corporations on the question of what their policy should be with respect to their sinking fund, whether they should invest in certain types of securities or return the money to the plants.

Cross Examination Interposed by Mr. Slaff.

We are consulted with respect to investments the corporations should make of funds they have available. I have handled that myself directly in a great many instances. We advise them from time to time as to what in our judgment are sound and prudent investments for them to make in the light of circumstances surrounding their corporate existences and conditions at the time.

(Colloquy between Counsel and Examiner with respect to objections on admissibility of Exhibits 132 and 133.)

Cross-Examination Resumed by Mr. Booth.

My testimony is that under the instructions stated to me as a predicate it is desirable for these companies to invest their depreciation or amortization moneys in Government securities. I did not express the opinion in my testimony that was desirable for this company to invest this money in Government securities as shown on Exhibit 132. I was only showing what the yield would be on risk-free investments if the funds were used in such investments. I have not attempted to in any way say what they should do or how they should handle it. If they were trying to accomplish the investments on a risk-free basis, it would be reasonable and proper to use this type of security. I am not making any suggestion or expressing any opinion that it is desirable for this company to put its amortization moneys in risk-free securities. I have made no investigation of the company's financial structure. I know they have bonds outstanding, but I do not know the amount. I happen to know they are 6% bonds. That is all I know about them. I have not explored with the company at all the question as to whether or not it would be more desirable for the company, if it wanted to make a sound, prudent investment, to invest this money in the purchase of its own bonds. I have given no consideration to that subject. I have not consulted with the company respecting whether or not it is desirable for the company to invest its money in additions to the property; I have not considered that in any way.

1019 In the course of my work and experience with the bank I have advised corporations as to how to invest their money. I have specialized on that for about two years or more. I have studied the problem of utility financing, but it is very seldom in general practice that I have ever found utilities, particularly operating companies, investing funds themselves. I am familiar with the fact that utilities do invest earnings in properties, in normal properties and additions. Generally speaking, the utility industry is a very young industry and is growing. They have a good deal of financing to do, not only through normal issue of securities, but they have gone ahead and used a lot of their own money, more than their depreciation reserves, for building up property. Talking generally, it is not unusual for utilities to use their depreciation charges for the purpose of paying for current additions to property.

(EXHIBITS 132 and 133 were offered and received in evidence, over the objection of counsel for each of the two Commissions, to whom exceptions were allowed.)

Cross-Examination by Mr. Slaff.

You have asked me as the basis for a hypothetical question to assume that defendants had $4,000,000 annually as the result of their charges for amortization; that they had a bond issue outstanding amounting to approximately $40,000,000 par at 6% interest; that in addition to that the company also was faced with the fact that it had to spend approximately $1,500,000 a year for additions to its property; that the record showed that in the last three or four years the income of the company on its investment approximated 10 or 12% per year; and that it was also faced with a problem as to whether or not it should invest this $4,000,000 a year in Government securities of the type which I have described; and you asked me whether or not I would consider it a sound and prudent act for the management of that company to take this $4,000,000 a year and either retire part of its bonds or invest that $4,000,000 or a part of it to cover additions to its physical property. So far as the hypothetical case that you have set up before me is concerned, I do not see any reason why those factors should not be given consideration. I think I would have to have more detail as to the type of bond that it is. I mean, obviously a natural gas or pipeline bond does not qualify as a good trust fund investment. It is not that kind of security. I think it depends upon what we are trying to accomplish with the funds. If this fund is something that is to remain intact over the period of years where it must be sure that it is going to be returned, I would want to see that it is going into risk-free investments, and I am not going to put it into a pipeline or into bonds of that type of company.

If a fund is segregated for a specific purpose, that is one thing. If it is a question of managerial policy or business judgment as to what they should do with it, that is another. It depends upon what you are trying to accomplish. If I am charged with the responsibility of seeing that $4,000,000 a year is taken out and placed in a position where I am sure that it is going to be returned to me within a 15-year period, I am going to be absolutely certain—I am sure any trustee would be—that those funds are going to be put in such securities that they would be assured of their principal and interest. It gets down to a question of business judgment as to which way you are going to handle it.

1020 *Cross-Examination by Mr. Booth.*

I am not in position, without knowing more about the particular bonds in question, to pass upon the question of judgment involved and whether or not the management of defendants should invest in Government securities at a return of only 1½% rather than paying off its outstanding bonds, which it will be compelled to retire sooner or later at 6% interest. The question of where you are going to apply the depreciation funds of any utility obviously is entirely one of judgment. In determining whether you will put the money back in the property you might think that is going to earn 6% or 10%, but you have no way of knowing. As to the retirement of the outstanding bonds it might not accomplish the purpose for which you are taking the amortization fund. As I understand it, the amortization fund that I was asked about would be one where you take accumulations of funds over a period of 15 years and return the principal and interest at the end of that 15-year period. It is to be used for the purpose of returning to the investors the money they put in the enterprise.

(Objection by Company Counsel to question by Commission Counsel sustained.)

I am familiar with the fact that utility companies are entitled under the law, normally, to obtain a fair return over and above their operating expenses. I am also familiar with the normal charges to operating expenses that are made by utility companies. One of those normal charges made by utilities is the charge for depreciation. Some utilities base their depreciation on the straight-line and others use the sinking-fund method and I am familiar with those facts. As to whether it makes a difference to the consumer in the rates that he would be required to pay, where a company uses the sinking-fund method in investing its depreciation funds and invests depreciation funds in Government bonds bearing an average yield of 1.52% or in the retirement of the utility's own bonds which bear a coupon rate of 6%, I cannot say that I have seen that particular question enter into it from what I have examined. (Objection by Company Counsel and questioning discontinued.) If these companies have available $4,000,000 a year and bonds bearing 6% interest, I would say that it would be a prudent act of management to invest and use that money to retire a part of those bonds when it can only obtain 1.5% by investing in Government securities. In other words, I would say that if the company can save interest through the investment of a part of their funds, that is the thing we are advising them to do all the time. I mean, the question of refinancing is obvious. There is a saving in there.

Redirect Examination by Mr. Morgan.

If the bondholder and stockholder are synonymous and the same person, as Mr. Booth suggested, and the money is used to retire the bonds, and the lesser amount is accumulated and turned over to the stockholder and he is required to surrender his bonds, he would be putting his money back into the risk after it comes back to him as a stockholder, and he must exercise his judgment to do that or put it into some risk-free security that will accumulate a sum sufficient to get him all of his money by the end of the 15-year period. So if the stockholder and the bondholder is the same man, it does not matter whether you retire the bonds or whether you handle it as a fund and return it through the liquidation of the corporation. He is going to have to put it to risk of some sort of investment, such as I have described here or he will not get his money back.

1021 J. G. DICKINSON, recalled by defendants, testified:

Direct Examination by Mr. Morgan.

(September 8, 1939.)

I have testified before in this case. In my original testimony, I stated that I am the superintendent of production of Texoma Natural Gas Company. I have under my supervision the lease and land departments, the geological department, the accounting department, so far as the Amarillo office is concerned, and the production department. In connection with my duties, I have the supervision and direction of the activities conducted by the several departments under the immediate supervision of the heads of those departments. I award the drilling contracts and execute those contracts for the company. In that connection, I have kept abreast of the contract prices or costs of drilling wells throughout that part of the field in which we have leases.

Since I was on the witness stand before, I have caused to be made under my direction an estimate of the recoverable reserve of gas down to an assumed abandonment pressure of 25 pounds, as of August 1, 1931, underlying the leases owned by Texoma as of January 1, 1939. I picked August 1, 1931 as the date of computing these reserves for the reason that it was the date those reserves were acquired by Texoma. That is it was the effective date of the transfers of the reserves to Texoma.

I used the same recovery factor that was used by the geologists Peterson, Hughes and Thompson, in connection with the reserves which they have brought into the record, which was 90 percent.

As of August 1, 1931, underlying the acreage owned by Texoma on January 1, 1939, computed on a pressure basis of 16.4 pounds per square inch, the estimated recoverable reserves underlying such acreage were as follows:

At zero pounds, abandonment pressure	2,505,680,723 M.C.F.
At 25 pounds	2,349,536,607 M.C.F.
At 50 pounds	2,187,387,385 M.C.F.
At 75 pounds	2,025,240,991 M.C.F.
At 100 pounds	1,869,096,876 M.C.F.
At 125 pounds	1,706,947,653 M.C.F.

I caused Mr. Peterson to reduce to writing an explanation of the methods employed by him in determining these reserves as of the date mentioned. I have this memoranda with me.

(At this point counsel handed the reporter a document dated "Aramillo, Texas, August 24, 1939", addressed to "J. G. Dickinson, Office", captioned "Explanation of Method Used in Determining Reserves As of August 1, 1931, On Acreage Owned by Texoma Natural Gas Company, January 1, 1939", and requested that it be marked as an exhibit for identification. At the direction of the Examiner, the document was marked Exhibit 134 for identification.)

I have recently made contracts for drilling wells for Texoma. We are currently drilling four wells in Moore County. We have drilled other wells during the year 1939. The prices stated by the witness Stoddart, a member of Mr. Hamilton's staff, who testified concerning the reproduction cost new of Texoma's wells, that $4 per foot
1022 in Moore County, $3.50 per foot in Hutchinson County, and $3.25 per foot in Carson and Gray Counties are the current contract prices paid in those areas. They were the contract prices on June 1, 1939 and for several years prior to that time. The differential in price between Gray and Carson Counties and Moore County is explained by the difference in depth of the wells. This difference in depth requires more time for the drilling contractor to withdraw and run his drill pipe when he changes bits. There is also a difference in the formation drilled. In the Moore County area the contractors more ofter lose circulation with its attendant difficulties and expenses. There is a difference in the amount of transportation involved in drilling wells in Moore County and in Gray and in Carson Counties, as a rule. Contractors operating in Moore County are further removed from drilling tool supplies than are contractors operating in Gray and Carson Counties. The price for drilling in Gray and Carson Counties is $3.25 a foot. The customary price in Hutchinson County is $3.50 a foot. Texoma has not drilled any wells recently in Hutchinson County. However, the price of $3.50 per foot is the customary price there. In Moore County the price is $4 per foot. This price per foot includes the drilling of the well from the top to the bottom.

In every case in the drilling of a gas well the actual drilling of the producing formation is done with cable tools. The upper part of the hole down to the top of the gas producing horizon is drilled with rotary tools. The rotary tools are then moved out and the standard form rig is moved in and cable tools are rigged up. The actual drilling of the gas producing formation is done with cable tools, for the reason that the well would be seriously damaged if the mud-laden fluid and water used in rotary drilling were allowed to enter the gas producing formation.

This $4 a foot, or whatever the price happens to be, depending, of course, on the location, covers the drilling by rotary and by cable tools. As a usual thing the drilling of the part of the hole which is done by cable tools is more expensive for the contractor. This condition is brought about by the fact that as the drill goes down below a gas-producing or gas-pay streak, the gas does not lift the cuttings out of the hole. The contractor is not able to keep water down to mix the cuttings with, and it is a question of just sitting there and pounding the stuff into dust, almost, before he can go ahead.

The term "day work", referred to by Mr. Stoddart in connection with his testimony on Exhibit 125, is intended to cover contingencies that are not provided for in the contract and which usually cannot be anticipated. The contractor is obligated to finish the well to its total depth under the contract price per foot. Day work is provided for situations which may happen after the contract for drilling is completed. In other words, it may be necessary to retain the contractor on the well after he has drilled it down to its full depth.

For example, we may wish to conduct some cleaning out operations after the drilling is completed. Sometimes the hole will bridge. That means the sides of the well will cave in and jam off the drilled portion so that the flow of gas is either cut off or restricted. In that kind of a cave-in, we have the contractor run the tools back in the hole and drill it out. That day work is provided for in the contract itself, and the pay for this work is $90
1023 per 24-hour day. That is the prevailing contract
price for that type of work in the field. That price does not vary in different portions of the field like the footage part of the contract. In some of Texoma's wells no day work is required. We are able to complete the well without any day work. In others, it may require five or six days or longer. Our experience has been that the average amount of day work amounts to about one day where the well is completed in a normal manner. (Motions to strike above testimony by Counsel for the two Commissions denied.) I do not have a record of the day work that was performed on the wells now belonging to Texoma but which were drilled prior to Texoma's purchase of these wells.

I have a copy of one of those drilling contracts currently in use in the field.

(At this point counsel handed the reporter a document captioned "Drilling Contract" bearing the date in the first line, 16th of August, 1939, and requested that it be marked for identification. At the direction of the Examiner the document was marked Exhibit 135 for identification.)

Exhibit 135 is a copy of the contract which we executed with the drilling contractor for the drilling of a well on one of Texoma's leases. That contract was executed on the 16th of August, 1939 and is at present being performed.

1024 S. LEROY MILLER, a witness for defendants, testified:

Direct Examination by Mr. Hedrick.

(September 8, 1939)

I am the same S. Leroy Miller who was on the witness stand day before yesterday. I live at Niles Center, Illinois. My place of business is at Twenty North Wacker Drive, Chicago, Illinois. I am in charge of the accounting departments of Natural Gas Pipeline Company of America and Texoma Natural Gas Company. I received my academic training in accounting at Northwestern University. From January, 1925, to October 30, 1930, I worked for the Empire Companies, with headquarters at Bartlesville, Oklahoma. My work with that company covered various branches of accounting.

Since November 1, 1930, I have worked for the Natural Gas Pipeline Company of America and Texoma Natural Gas Company in the supervision of various branches of accounting. From November 1, 1930, to June 1, 1931, I supervised the accounting work in connection with construction cost records of the two companies. From June 1, 1931, to May, 1937, I supervised the accounting records of the Texoma Natural Gas Company and handled such other work as the tax returns and special reports for both companies. Since May, 1937, my work has covered the supervision of the accounting records of both companies. I work under the direct supervision of Mr. S. E. Campbell, Secretary of the two companies.

(At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company—Earnings Statements for Calendar Years 1932 to 1938, Inclusive," and requested that it be marked for identification. At the direction of the Examiner, the document was marked Exhibit 136 for identification.)

I have prepared for the purpose of this case Exhibit 136 showing the earnings statements of defendants for the calendar years 1932 to 1938, inclusive. This exhibit is a statement of the earnings and expenses of the two companies separately and of the companies combined, after eliminating inter-company income and expense. This exhibit was prepared to show in general the information purported to be shown in Exhibit No. 15 introduced through Mr. Woodford, an accountant for the Illinois Commerce Commission. This exhibit is arranged in slightly different order from Exhibit 15 so as to present what, in my opinion, is a more logical sequence of statements. Also, certain expenses have been reclassified so as to make the statements, in my opinion, more uniform. The exhibit is divided into three parts.

Pages 1 to 3, inclusive, reflect the combined revenues and expenses of the two companies after eliminating inter-company transactions. Pages 4 to 9, inclusive, reflect the revenue and expenses of Natural Gas Pipeline Company of America. Pages 10 to 15, inclusive, reflect the revenue and expenses of Texoma Natural Gas Company. These statements were prepared to show the revenue and expenses as reflected by the books of the companies and were not taken from the companies financial statements, as were
several pages of Exhibit No. 15. The financial state-
1025 ments do not present final information, since they
were prepared as of a certain day or for a certain
period. Although in accord with the companies' books at the date they were prepared, the financial statements do not reflect subsequent adjustments that affected the period. The statements in this Exhibit No. 136 were prepared for the period starting January 1, 1932, since the companies considered that date as the beginning of permanent operations. All prior operations were considered preliminary and the resulting deficit of $7,996.92 was capitalized, on the companies' books. Page No. 1 presents in condensed form a statement of profits and losses of the two companies combined, after eliminating the inter-company transactions, by years and for the total period. This statement shows a total net profit for the period of $8,244,435.-

79 as compared with $8,207,995.08 shown on page 16, line 38, Column 1, of Exhibit No. 15. This difference between the two statements, amounting to $36,440.71, is accounted for by five items.

1. Loss for 2½ months of 1931 included in Exhibit No. 15, $7,996.92. This amount is the net loss for the 2½ months from October 15, 1931, to December 31, 1931, which, as I have mentioned before, was considered a period of preliminary operations and this loss was capitalized on the books of Natural Gas Pipeline Company of America.

2. Write-off of corporate expenses included as 1931 expense in Exhibit No. 15, $5,979.02. This amount reflects the total expense in organizing Natural Gas Pipeline Company of America and was charged off on the books of the company in the year 1935.

Questions by the Examiner.

The first figure I am comparing is shown on line 13, page 1, of Exhibit No. 136 and the figure $8,207,995.08 is shown on page 16, line 38, column 1, of Exhibit No. 15.

Direct Examination Resumed by Mr. Hedrick.

The amount $7,996.92, to which I have referred, appears in Exhibit No. 15, on page 7, line 24, column 1 and is designated A. The next item, I believe, we just identified, was on page 16. That is shown in line 31, column A, of Exhibit No. 15. When I refer to Exhibit 15 I am referring to it as corrected by an errata sheet, Exhibit 53.

This amount of $5,979.02 reflects the total expense in organizing the Natural Gas Pipeline Company of America and was charged off on the books of the company in the year 1935. This amount is not applicable to any definite year, and I have therefore considered it as an unallocated charge to surplus. In other words, I have not considered this as an expense of any particular year.

3. Write-off of bond expense applicable to 1931, included in Exhibit No. 15 as expenses of the years 1936 and 1937, $28,210.35. There are quite a number of items in this Exhibit No. 15 which have been combined, and it is rather difficult to identify some of these. This adjustment of bond expense is reflected in two items in Exhibit No. 15. On page 6, line 15, column G is an amount of $19,916.67. That

is the adjustment on the books of the Natural Gas Pipeline Company of America. That is an item of amortization of bond discount and expense. That item is a writeoff, 1026 an adjustment of the bond expenses for Natural Gas Pipeline Company of America. It is shown on page 6 of Exhibit No. 15 on the line with organization expense write-off, but it is in fact an adjustment of the bond expense and had nothing to do with the organization expense. As I recall from my analysis of Exhibit 15, the other part of that adjustment was combined with other figures shown on page 14 of Exhibit No. 15. I am unable to identify that balance from this particular statement, but the amount was included in the year 1936. I would have to analyze each of those figures to state in just which one of those items it is included. I will be prepared to do that on cross examination as requested. I will prepare a breakdown of each one of these amounts to which we have been referring and to which we will refer so that they can be definitely located in Exhibit No. 15, by line and by page number.

This amount $28,210.35 reflects the unamortized portion of the cost of tax stamps affixed to the original bond issued, and was charged to surplus in 1937 as being applicable to 1931 in accordance with the agreement between the Natural Gas Pipeline Company of America and the Bureau of Internal Revenue. From the total of the three items I have just enumerated there should be deducted the total of the following two items in accordance with the books of the company. These charges were made to put the books more in line with the settlement with the Bureau of Internal Revenue concerning tax liability.

4. Surplus adjustment of 1938 taxes not included in Exhibit No. 15, $2,966.30. This amount is an adjustment of the accrual for 1938 income taxes of the Natural Gas Pipeline Company of America. This adjustment was recorded on the books of that company in the first part of 1939 but was not reflected in Exhibit No. 15.

5. Surplus adjustment of 1938 depreciation not included in Exhibit No. 15, $2,779.28. This adjustment of depreciation was made on the books of the Natural Gas Pipeline Company of America in the first part of 1939 and is an adjustment affecting the depreciation as recorded on the books of that company during the year 1938.

The next total of these five adjustments, amounting to

$36,440.71, is the difference between page 1 of this Exhibit 136 and the total shown in line 38, column 1, page 16, of Exhibit No. 15.

Page No. 2 supplements page No. 1 and reflects in some detail the information shown in lines 1 and 2 of page No. 1. This statement reflects the operating revenue and operating expenses for the two companies after eliminating inter-company income and expenses.

These last five items just summarize the differences.

Page No. 3 shows the combined surplus account for the Natural Gas Pipeline Company of America and the Texoma Natural Gas Company after eliminating inter-company transactions. Line 1 shows the combined profits and losses for the year and the period. Line 2 shows dividends declared and paid. Line 3 shows the yearly balance of net profits after payment of dividends. Lines 4 to 7, inclusive show the details of other surplus charges, and line 9 shows the combined deficit at the end of each year. The dif-
1027 ference between the deficits of $939,753.58 shown on
page No. 3, line No. 9, column 8, of this Exhibit No. 136, and the corresponding item amounting to $942,004.92 shown on page 16, line 40, column 1 of the Exhibit No. 15 is accounted for in two items:

1. Loss for 2½ months of 1931 included in Exhibit No. 15 but capitalized on the companies' records $7,996.92. This is the loss for the 2½ months of preliminary operations that was capitalized on the books of the Natural Gas Pipeline Company of America and is the same item that I have referred to previously.

2. Less surplus adjustment of taxes and depreciation for the year 1938 not included in Exhibit No. 15, $5,745.58. This amount is the total of the two 1938 surplus adjustments referred to in the explanation of page No. 1, namely, the adjustment of income taxes for the Natural Gas Pipeline Company of America, $2,966.30, and adjustment of depreciation of Natural Gas Pipeline Company of America, $2,779.28. The net difference between the amount of the loss for the 2½ months of 1931 as reflected by the books of the Natural Gas Pipeline Company of America, amounting to $7,996.92, and the adjustment of taxes and depreciation as reflected on the books of the Natural Gas Pipeline Company of America, amounting to $5,745.58 is a net difference of $2,251.34, which, as I have stated, is the difference between the amount shown on this page 3, line

9, column 8, and the comparable item shown on page 16, line 40, line 1, of Exhibit No. 15.

Page 4 presents in condensed form the profits and losses of the Natural Gas Pipeline Company of America, as reflected by the books of that company. This statement reflects a total profit for the seven years of $10,097,235.29 instead of the $13,813,992.34 shown on page 1, line 22, column 1, of Exhibit No. 15. The difference between these two exhibits, amounting to $3,716,757.05, is accounted for as follows:

I mean the difference between page 4 of Exhibit No. 136, that is, line 12, column 8 of that page and page 1, line 22, column 1, of Exhibit No. 15.

1. Depreciation omitted from page 1 of Exhibit No. 15, $2,669,744.05. During the first two years of the companies' operations the depreciation was not recorded on the books of the Natural Gas Pipeline Company of America. This depreciation was, however, recorded during the year 1934 but was not reflected on the financial statements, which had been previously prepared and which were the source of the information from which page 1 of Exhibit No. 15 was prepared.

Wherever I testified as to the source of Mr. Woodford's information, I based my statement on the source stated in his Exhibit 15 or his testimony concerning that exhibit.

Also for the year 1937 an adjustment of $400,000 was made in the depreciation and this amount, although reflected on page 6, line 22, column G, was not reflected on page 1 of Exhibit No. 15. In other words, Mr. Woodford has a page in his exhibit, showing the over-all adjustment, but he did not carry those adjustments to a particular
1028 page for the particular years. I could take Mr. Woodford's exhibit and by taking page 1 of Exhibit 15, together with page 6, line 22, column G, I would arrive at the final figure, but he did not do that in the preparation of page 1.

2. Bond discount and expense amortization omitted from page 1 of Exhibit No. 15, $258,410.18. During the year 1933 the amortization of bond discount and expense applicable to the year 1932 was recorded on the books of the Natural Gas Pipeline Company of America but was not reflected in the 1932 financial statements, which has been previously prepared and which were the source of the information used in preparing page 1 of Exhibit No. 15.

3. Interest adjustment for 1931 omitted from page 1 of Exhibit 15, $752,163.16. This is the amount of interest expense of Natural Gas Pipeline Company of America applicable to the period from October 15th to December 31, 1931. This interest adjustment is reflected on page 6, line 39, column A, of Exhibit No. 15, but was omitted in the preparation of page 1 of Exhibit 15.

4. Total of miscellaneous adjustments omitted from page 1 of Exhibit No. 15, $36,439.66. This adjustment is made up of a number of small items which I have not attempted to enumerate. I will list those small adjustments in the sheet which I am going to prepare later.

Total of adjustments omitted from page 1 of Exhibit No. 15, $3,716,757.05. These adjustments are shown on pages 6 and 7 of Exhibit No. 15 but should be carried throughout that Exhibit so as to give complete information.

Page No. 5 of this Exhibit No. 136 is divided into three parts: Operating revenue, operating expense, and gas account of the Natural Gas Pipeline Company of America. This statement shows the various accounts as reflected by the books, or, in other words, this statement shows page No. 2 of Exhibit No. 15 after applying the adjustments shown on page 6 of Exhibit No. 15, together with an adjustment of the 1938 taxes not included in Exhibit No. 15, amounting to $2,966.30. This adjustment of taxes has been previously discussed in connection with this Exhibit No. 136. Although there is some slight difference in application of the adjustments as reflected on the books of the Natural Gas Pipeline Company of America between this page No. 5 of Exhibit No. 136 and the adjustments shown on page 6 of Exhibit No. 15, these differences are between the years and the over-all difference is only the adjustment of 1938 taxes that I have just explained.

Page 6 shows the gas sales of the Natural Gas Pipeline Company of America both as to thousands of cubic feet and revenue and is comparable to page 3 of Exhibit No. 15. For the period of years shown the two exhibits agree in totals except that page 3 of Exhibit No. 15 does not reflect the adjustment of gas sales, which adjustment is shown on page 2, line 8, column C, of Exhibit 15. As to gas sales in thousands of cubic feet, the difference in quantities is caused by the fact that page No. 3 of Exhibit No. 15 reflects metered volumes and this page 6 reflects the billed volumes. In other words, this page 6 shows the total gas metered plus adjustments for the excess B.t.u.'s, or heat units of

the gas delivered over and above the contract base. In
other words, there is an adjustment made in the metered
volume of gas caused by excess British thermal units contained in the gas actually delivered. I have used the
1029 billed volumes and not the metered volumes. I believe I mentioned that for the period of years shown
on this statement that the only differences were the ones
that I had enumerated.

Page 7 shows a breakdown of other operating income and non-operating income. This page is comparable to page 4 of Exhibit No. 15 except that this page reflects adjustments shown on page 6 of Exhibit No. 15, and also includes, first, reclassification of interest on treasury bond and, second, reclassification of house rents in accordance with the company's present classification.

The interest on the treasury bond, which was a $1,000 bond held by the company was reflected originally on the books of the company both as an interest expense and as an interest revenue. That was one of the company's own bonds which was held in the treasury. These contra-interest items were eliminated in an adjustment on the books of the company so as to clearly reflect the interest income and the income expense of the Natural Gas Pipeline Company of America. At the time Exhibit No. 15 was prepared, the revenue from house rents was considered non-operating income; but this item was reclassified on the books of the company since the first of the year 1939 and this statement was prepared in accordance with the company's present classification. I find no fault with Mr. Woodford's exhibit in light of the records as they then stood.

Page 8 shows in detail the amounts of gas purchased and the amounts of gas used by the company. This page No. 8 is comparable to page No. 5 of Exhibit No. 15 except that this page No. 8 reflects the amounts paid for gas after applying all adjustments, and page No. 5 of Exhibit No. 15 does not include the adjustments of the amounts paid for gas as shown on page No. 6 of Exhibit No. 15.

Page 9 is a statement of the surplus account of the Natural Gas Pipeline Company of America and is comparable to page No. 7 of Exhibit No. 15. Although there are variations in the year by year totals between this page No. 9 and page No. 7 of Exhibit No. 15, caused by differences in the application of surplus adjustments, these differences wash out in total except for two items of $5,745.58 that were not included in Exhibit No. 15. These two items are the adjustments for taxes and depreciation which I have previously explained.

Page 10 presents in condensed form a statement of profits and losses of the Texoma Natural Gas Company as reflected by the books of that company, and is comparable to page No. 8 of Exhibit No. 15. This statement shows a net loss for the seven years of $1,852,799.50 as compared with a profit of $1,393,518.59, shown on page No. 8, line 34, column 1, of Exhibit No. 15. The difference between the total shown on this page No. 10 and the total shown on page No. 8 of Exhibit No. 15 is accounted for as follows:

1. Depreciation and depletion for the years 1932 and 1933 omitted from page No. 8 of Exhibit No. 15, $895,970.58.

During the years 1932 and 1933, the depreciation and depletion was not recorded on the books of the com-
1030 pany. However, during the year 1934 these amounts were recorded as applicable to the years 1932 and 1933, and should, therefore, be reflected in Exhibit No. 15. These adjustments of depreciation and depletion are reflected on page No. 14 of Exhibit No. 15, but are not included on page No. 8 of Exhibit No. 15.

2. Retirements of property omitted from page No. 8 of Exhibit No. 15, $2,351,340.74. This amount is the write-off of acreage that expired or was abandoned during the year 1933, and the loss on the sale of certain wells and leases during the year 1933. This amount of $2,351,340.74 that was omitted in the preparation of page No. 8 of Exhibit No. 15 is reflected on page No. 14, line 15, column 1, of Exhibit No. 15. From the total of these two adjustments that I have just explained should be deducted the amount of $993.23, which is the sum total of miscellaneous adjustments that I have not detailed, the net total of adjustments omitted from page No. 8 of Exhibit No. 15 being $3,246,318.09.

Page 11 is divided into two parts: Operating revenue and operating expenses of the Texoma Natural Gas Company. The first section of this statement explains in brief line 1 of page 10 of Exhibit 136. The second section of this statement explains line 2 of page No. 10. The difference between the amounts shown in the statement and those amounts shown on pages 12 and 13 of Exhibit No. 15, are caused principally by the omission from pages 12 and 13 of Exhibit No. 15 of adjustments shown on page No. 14 of Exhibit No. 15. Also pages No. 12 and No. 13 of Exhibit No.

15 do not reflect the reclassification of certain write-offs of retirements of property that were originally charged to operating expenses but were later reclassified on the books of the company.

Page 12 shows the gas sales of the Texoma Natural Gas Company, both as to thousands of cubic feet and the revenue. This statement also shows sales in thousands of cubic feet and is comparable in that respect to page No. 10 of Exhibit No. 15. The amounts of gas shown on pages 9 and 10 of Exhibit No. 15 under the captions "drilling wells" and "testing lines" were reclassified on the books of the company so as to more clearly reflect the revenue producing items and the items of expense.

Page 13 shows the details of the gas account and the gasoline account for the years 1932 to 1938, inclusive, and the totals for the period. This statement is comparable to page 11 of Exhibit No. 15.

Page 14 shows a breakdown of other operating income and non-operating income. Similar information in different form is shown on page 9 of Exhibit No. 15. However, since Exhibit No. 15 was prepared there have been certain reclassifications of income on the books of Texoma Natural Gas Company. These reclassifications of income pertain to interest income and house rents. In the first years of operation of Texoma Natural Gas Company the company did separate its interest income from its interest expense. However, during the later years it had been the policy of that company to combine interest income with interest expense and reflect the interest expense as a net amount. That interest has now been separated on the books of the company and is so reflected in this page 14 of Exhibit No. 136. As to house rents, as I have explained in connection with Natural Gas Pipeline Company of America, the house rents were classified as non-operating income on the books of Texoma Natural Gas Company at the time Exhibit
1031 No. 15 was prepared. However, in the first part of
1939 this account was reclassified to other operating income on the books of Texoma Natural Gas Company, and this page 14 was prepared in accordance with the company's present classification.

Page 15 is a statement of the surplus account of Texoma Natural Gas Company and is comparable to page 15 of Exhibit No. 15. While there are variations in the year by year totals between this page 15 of Exhibit No. 136 and page 15 of Exhibit No. 15, these differences wash out in the final total, both statements showing a loss for the seven years of $1,852,799.50 instead of a profit of $1,393,518.59 shown on page 8, line 34, column 1 of Exhibit No. 15.

Exhibit No. 136 was prepared from the books of the companies.

(At this point EXHIBIT 136 was offered and admitted in evidence without objection.

At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Balance Sheets and Statements of Plant and Equipment, December 31, 1931, to December 31, 1938, Inclusive", and requested that it is be marked for identification. At the direction of the Examiner, the document was marked Exhibit No. 137 for identification.)

I prepared Exhibit No. 137 and have a copy of it before me. This exhibit shows the year end balance sheets and statements of plant and equipment of the Natural Gas Pipeline Company of America, the Texoma Natural Gas Company, and for the companies combined after eliminating inter-company balances. This Exhibit No. 137 covers the same type of information shown in Exhibit No. 54 except that it reflects all end of year balances from December 31, 1931 to December 31, 1938, whereas Exhibit No. 54 does not show the balances prior to December 31, 1934, as Exhibit 54 omitted balances prior to December 31, 1934.

Page No. 1 shows the year end balance sheets for the companies combined after eliminating inter-company balances. This page 1 is comparable to page 5 of Exhibit No. 54.

Page 2 shows the year end balances of the plant and equipment accounts of the two companies combined and is a breakdown of line 3 of page 1.

Page No. 3 of this Exhibit No. 137 shows the year end balance sheets of the Natural Gas Pipeline Company of America as reflected by the books of the company and is comparable to page No. 1 of Exhibit No. 54. I have examined the balance sheets presented on page 1 of Exhibit No. 54 and have found that most of the items shown are correct. However, for the year 1934 Mr. Woodford's figures contain certain adjustments, which I was unable to identify, and which produced slightly different results than those I obtained. None of the balance sheets in Exhibit No. 54 reflect the adjustments disclosed on pages 6 and 7 of Exhibit No. 15, nor do they agree with the year end surplus account shown on page 7, line 27, of Exhibit No. 15. The balance sheets in Exhibit No. 54 for the years ended December 31, 1935, 1936, 1937 and 1938 were taken from the company's financial statements and do not reflect any subsequent adjustments.

1032 Page 4 shows the year end balances of the plant and equipment accounts of the Natural Gas Pipeline Company of America and is a breakdown of line 2, page 3. This statement is comparable to page 2 of Exhibit No. 54. In this statement of plant and equipment in Exhibit No. 137 the balances shown as of December 31, 1931 were obtained by analyzing job orders that were open at that date.

Page No. 5 shows the year end balance sheets for the Texoma Natural Company as reflected by the books of the company, and is comparable to page 3 of Exhibit No. 54. All balance sheets shown on page 3 of Exhibit No. 54 were taken from the company's financial statements and do not reflect subsequent adjustments. Nor do these balance sheets tie in with the surplus statement shown on page 15 of Exhibit No. 15.

Page 6 shows the year end balances of the plant and equipment accounts of the Texoma Natural Gas Company and is a break-down of line 3, page 5. This page is comparable to page 4 of Exhibit No. 54. In this statement of plant and equipment in Exhibit No. 137 the balances shown as of December 31, 1931, were obtained by analyzing job orders that were open at that date.

The information used in preparing these statements in Exhibit No. 137 was taken from the books of the Natural Gas Pipeline Company and the Texoma Natural Gas Company.

(EXHIBIT NO. 137 was offered and admitted in evidence without objection.

At this point counsel handed to the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Statement of Operating Revenue and Expenses, Statement of Plant and Equipment Exclusive of Leaseholds, Statement of Accumulated Expenditures for Leaseholds, December 31, 1931, to December 31, 1938, Inclusive", and requested that it be marked for identification. At the direction of the Examiner, such document was marked Exhibit No. 138 for identification.)

I prepared Exhibit No. 138 and have a copy of it before me.

This Exhibit No. 138 was prepared to show by years and for the total period of years three classes of information: (1) Operating Revenue and Operating Expenses; (2) Year Ended Balances of the Plant and Equipment Accounts, Exclusive of Leaseholds; and (3) the Accumulated Expenditures for Leaseholds. This information is presented in three groups: Pages 1 and 2 cover the information for the companies combined; pages 3 and 4 cover the information for the Natural Gas Pipeline Company of America, and pages 5 to 8, inclusive, cover the information for the Texoma Natural Gas Company.

Page 1 shows in some detail the operating revenue of the two companies after elminating inter-company items. Page 1 also shows the operating expenses of the two companies after eliminating inter-company items, and these expenses are divided into two groups: (1) Operation and General Expenses and (2) Maintenance Expense. The item of
1033 net earnings from operations before amortization and other charges is, of course, the excess of the gross operating revenue over the total operation, maintenance, cost of retirements, and general expenses. This item of net earnings from operations before amortization and other charges is shown by years from 1932 to 1938, inclusive, and the total accumulated for the seven years. Line 35 of this page 1 shows for the two companies the accumulated net earnings from operations before amortization and other charges from the beginning of the year 1932 to the end of each of the successive years shown on this page. Line 36 shows the annual average of net earnings from operations before amortization and other charges and reflects the average net earnings from operations before amortization and other charges to the end of each period of years starting with the year 1932. In other words, this annual average might be explained as the result of dividing the total net earnings from operations before amortization and other charges for the period of years (line 35) by the number of years' operation since January 1, 1932.

In other words, take column 5 "Year 1936" the figure on line 36 is obtained by dividing the figure on line 35 by 5. The same is true in the other columns in the exhibit.

Cross-Examination Interposed by Mr. Slaff.

By the term "total cost of retirements", page 2, line 30, I mean the expense of labor and materials used in retiring items of property. That is to say gross amounts of labor and expense involved in the retirement of property. Page 2 shows the balances of the plant and equipment accounts for the two companies combined, exclusive of leaseholds at the end of each year.

Direct Examination by Mr. Hedrick Resumed.

There is a typographical error in the caption. The word appearing "Pland" should be "Plant".

This statement also shows the expenditures of leaseholds to the end of each year.

Page 3 shows the operating revenue, operating expenses, and net earnings from operations before amortization and other charges of the Natural Gas Pipeline Company of America. This statement also shows the total net earnings from operations before amortization and other charges for each period of years since the start of operations, as reflected by the company's books, and the average net earnings from operations before amortization and other charges for each period of years since the start of operations. These last two items were calculated exactly the same as the comparable items explained in connection with page 1.

Page 4 shows the balances of the plant and equipment accounts of the Natural Gas Pipeline Company of America at the end of each year during the period of December 31, 1931, to December 31, 1938. The balances shown on this statement at December 31, 1931, were obtained by analyzing the job orders that were open at that date.

1034 Page 5 shows the operating revenue, operating expenses, and net earnings from operations before amortization and other charges of the Texoma Natural Gas Company. This statement also shows the accumulated net earnings from operations before amortization and other charges for each period of years since the start of operations and the average of the net earnings from operations before amortization and other charges for each period of years since the start of operations.

Page 6 is divided into two parts. Lines 1 to 19, inclusive, show the year end balances of the plant and equipment accounts, exclusive of leaseholds, and line 20 shows the accumulated expenditures for leaseholds. The balances at December 31, 1931 were obtained by analyzing the job orders that were open at that date. Line 20 is supplemented and explained by the following pages 7 and 8.

Page 7 shows the details of the leasehold account at December 31, 1931. This statement shows the amounts expended to acquire acreage from the various companies, as reflected by the books of the company, to December 31, 1931. Also shown on this statement are the amounts of construction overheads apportioned to this account. This sheet 7 details and explains the December 31, 1931 total accumulated expenditures for leaseholds shown on page 6, line 20, of this Exhibit No. 138.

Page 8 shows in some detail the amounts expended year by year for leaseholds and the total net expenditures for leaseholds to the end of each year from December 31, 1931 to December 31, 1938. This sheet 8 is supplemental to page 6 and more fully explains line 20 of page 6, and line 21 of page 2. On this page 8 I show the expenditures for leaseholds year by year, the cost of any property exchanged for leaseholds, the amount of cash received in any sales of leaseholds, the boot received in any exchanges of leaseholds, the net result of which is the additional expenditures for leaseholds. This statement shows that according to the books, the company had expended to December 31, 1938, a total sum of $15,893,513.08.

By the term "boot received," I mean cash received in an exchange of property, over and above the property received. Where we trade one lease for another and get $5,000 or $1,000 in addition, we call that boot received.

I obtained the figures contained in Exhibit No. 138 from the books and records of the companies.

(EXHIBIT No. 138 was offered and admitted in evidence without objection.

Offer of proof by Company Counsel and objections by counsel for the two commissions.

EXHIBIT No. 131 was offered and received in evidence with the understanding that defendants would be permitted to furnish additional sheets correcting any errors in arithmetic that appeared in that exhibit. Counsel for the two Commissions objected to this exhibit and were allowed exceptions.

EXHIBIT No. 134 was offered and received in evidence without objection.

1035 EXHIBIT No. 135 was offered and received in evidence over the objection for each of the two Commissions, who were allowed exceptions.)

1036 S. E. CAMPBELL, recalled by the defendants, testified as follows:

Direct Examination by Mr. Morgan.

(September 8, 1939)

I have testified in these proceedings before. I am secretary of defendants. As one of the duties of my office, I have custody and supervision of the records and books of account of both these corporations.

I have prepared and caused to be prepared under my direction some computations to be offered in this case that are predicated on the exhibits and testimony already in the case. In preparing those exhibits, I was instructed by counsel as to the subject matter to be covered. I prepared them in the form advised by counsel. I do not take the responsibility for the forms. The figures came from other evidence already in the case and I am prepared to point out that evidence in the course of my testimony.

I have prepared a total of four computations.

(At this point, counsel handed the reporter a 1-page document entitled "Computation Based on Field Price of Gas to Be Recovered by Texoma Natural Gas Company after January 1, 1939, and Costs of Drilling, Equipping, Maintaining, and Operating Wells. Witness S. E. Campbell" with the request that it be marked for identification. At the direction of the Examiner, the document was marked Exhibit 139 for identification.)

I have before me Exhibit 139. This exhibit is a computation to show the difference between, as termed in this exhibit, the gross value at the head of the well at the present field price of 4 cents per M.C.F. on the recoverable gas at 25 pounds abandonment pressure from Texoma's leases, and the cost of lifting this gas to the well head.

In the first line following "Total recovery January 1, 1939, through 1954 (from testimony of Dickinson and Bussard)," we have the figure 790,280,674 M.C.F. That figure is taken from the testimony of Mr. Dickinson and from a report prepared by Mr. Bussard, used in connection with his Exhibit 117. That is the total quantity of gas which, according to their testimony, Texoma will be able to recover from its wells by the end of 1954.

In line No. 2, after the words "Gross value at the head of well at present field price of 4 cents per M.C.F." appears the amount $31,611,277. The figure 4 cents per M.C.F. was taken from the testimony of Mr. Dickinson, Mr. Hughes, and others who have testified in this hearing. The sum of money set out at the end of that line was obtained by multiplying the total volume shown in line No. 1 by 4 cents per M.C.F.

In line No. 3, captioned "Operation and Maintenance Expense from January 1, 1939, through 1954 (from an analysis of Exhibit Nos. 102 and 117)" appears the figure $9,805,029. Those figures were taken from an
1037 analysis of Exhibits 102 and 117, and represent the operation and maintenance expense of the production department applicable to the production of gas for the period January 1, 1939, through to the end of 1954. Exhibit 102 was prepared by and offered through Mr. Dickinson, and Exhibit 117 was prepared by and offered through Mr. R. M. Bussard. At the end of line 4, captioned "Capital expenditures of production department as of June 1, 1939 (from an analysis of Exhibits 102 and 117)" appears the figure $4,741,642. That figure was likewise taken from an analysis of Exhibits 102 and 117 and represents the capital expenditures for wells, lease equipment, and clean-out equipment. That was the figure to which Mr. Dickinson testified and which was carried into Mr. Bussard's Exhibit 117.

In line 5, captioned "Reproduction cost new, less viewed depreciation of wells completed and producing as of June 1, 1939 (from Exhibit 125)" appears the figure $2,892,755. That figure was taken from Exhibit 125 prepared by and offered through Mr. Hamilton and his associates.

I added together the sums shown in lines 3, 4 and 5 and arrived at the total shown in line 6, captioned "Total expense, maintenance and capital cost." The figure shown in line 7, captioned "Difference between amounts shown in lines 2 and 6" was arrived at in the manner indicated in the caption.

I have the working papers underlying all these figures and they will be available to Mr. Johaningsmeir and Mr.

Woodford and any other accountants whom the commission may delegate to check them with me.

(EXHIBIT 139 was offered in evidence over objections of counsel for each of the Commissions. The Examiner announced he would withhold his ruling on the admissibility of Exhibit 139 until the next session of the hearing.

Counsel handed the reporter a document composed of 2 mimeograph pages captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company (Combined) Earnings Statement Covering Entire Life of Project" with the request that it be marked for identification. At the direction of the Examiner, the document was marked Exhibit 140 for identification.)

I have before me Exhibit 140 which was prepared by me and under my direction. This exhibit covers a combined earnings statement of the companies for the entire life of the project, beginning January 1, 1932, and extending to and including the end of 1954. The period from October 15, 1931, to the end of that year is not covered by the exhibit for the reason the books of the company were set up as of January 1, 1932. All previous transactions were capitalized.

Page 1 is a summary sheet which reflects the total revenues of the companies combined, the total operation, maintenance, and retirement expense, the total cost of the capital expenditures including replacements, gas reserves and working capital and the liquidating salvage value. It reflects the total revenue remaining after taking out the capital expenditures anad reflects the average rate of return on the average investment for the life of the project. By the last expression, I mean the average annual rate of return on the average annual investment throughout the life of the project.

1038 Under the sub-caption "Revenue," line 1 "From domestic sales," the figure recorded in column 1 was taken from Exhibit 138 to which Mr. Miller testified as being taken from the companies' books. In Mr. Kesinger's statement on future sales and revenue, he expressed his opinion that the average yearly income from domestic sales from January 1, 1939 on, as long as sufficient gas is available to meet the full domestic requirements, would not exceed the average realized for the three-year period 1936, 1937, and 1938.

For the period from January 1, 1939 to November 1, 1953, from a study prepared by Mr. Bussard, under Mr. Kesinger's supervision, there will be sufficient gas available to meet the domestic requirements. For this period of time we have applied to each year the average of the three-year period 1936, 1937, and 1938. After November 1, 1953, the amount of gas available will apparently progressively diminish up to the end of 1954. These figures were worked out in Mr. Bussard's study and we have used those figures and computed the amount of money for that period of time strictly in accordance with the companies' domestic sales contracts.

Those figures for the decreasing quantity of gas to be produced from and after November 1, 1953, on through the year 1954 were the same figures employed in the computation set up by Mr. Bussard in his Exhibit and explained in his testimony.

The figure set out in column 3 is the sum of the amounts shown in columns 1 and 2. The figure $9,752,872 shown in column 4, is the yearly average for the entire period and is obtained by dividing the amount contained in column 3 by 23.

The figure in line 2, captioned "From industrial sales" was obtained from Exhibit 138. In Mr. Kesinger's testimony on future sales revenues, he stated that in his opinion the income from industrial sales, as long as gas was available to meet all the industrial requirements, would not exceed the average realized from industrial sales through the years 1936, 1937, and 1938. From Mr. Bussard's study, gas available will meet the requirements of the industrial sales from January 1, 1939 to September 1, 1952.

For this period, we have arrived at the total revenue by applying to each year the average realized by the two companies during the three-year period 1936, 1937, and 1938. After September 1, 1952 to November 1, 1953, the gas available for industrial purposes progressively diminishes until by November 1, 1953 there is no more gas available for industrial sales, except that which would fall under domestic contracts. So during this period from September 1, 1952 to November 1, 1953, we have applied the gas available for industrial purposes to the industrial contracts, carrying the higher prices, dropping out the lower price contracts. In computing the revenues from industrial gas during that period of decline from September 1, 1952 to November 1, 1953, we have only discarded so much of the lowest price gas as will not be available and have applied the available gas to the highest price gas under our contracts for industrial gas during that period.

Column 3 is the total of columns 1 and 2. Column 4 is the yearly average for the entire 23-year period. The item "Revenue from Texoma's Field Sales" represents sales to the Lone Star Gas Company and the Coltexo Corporation. In Mr. Dickinson's testimony, he stated that the wells from which Coltexo was taking gas would be abandoned by the end of 1941. During this period the amount available
1039 from these wells to Coltexo Corporation progressively
diminishes, and these amounts taken from Mr. Bussard's study were used in computing the revenue from the Coltexo Sales. These figures appear in column 2. The figures in column 1 are taken from Exhibit 138 and Mr. Miller's testimony.

The Lone Star Gas Company sales extend throughout the period at an amount equivalent to the quantity of gas they took from Texoma during the year 1938. That is to the end of 1944. After 1944, the gas available from the wells serving the Lone Star Gas Company progressively diminishes and the amounts used were taken from Mr. Bussard's study which reflects these quantities by years. There is no allowance in these figures for any gas that might be produced from other wells to be drilled down there where the wells connected with the Lone Star Gas Company are located.

The price used in determining the income from these two sales is the price which is now contained in the sales contracts with these two companies and is based on the present price under the existing contracts. Column 3 is again the totals of column 1 and 2, and column 4 is the yearly average for the 23 years. Line 4 is simply the total of lines 1, 2, and 3.

Passing on to line 5, caption "Revenue from gasoline sales" the figures contained in column 1 were taken from Mr. Miller's Exhibit 138. The amount shown in column 2 was taken from Mr. G. M. Davidson's testimony as reflected in Exhibit 121. The amount shown in column 3 is the total of lines 1 and 2 and the amount shown in column 4 is the yearly average for the 23 years.

In line 6, caption "Revenue from other operating income" in each one of the 4 columns, this item represents house rents less the cost of maintaining the company houses. The amounts shown in column 1 were taken from Mr. Miller's Exhibit 138. The maintenance portion that was deducted in arriving at the amounts shown in column 2 was taken from Exhibits 94 and 98 to which Mr. Powers and Mr. W. H. Davidson testified. The gross revenue from which this maintenance was deducted was based on the company's present rent schedule for company houses and covers the present houses as well as the future houses to be constructed. It is assumed that all the houses now in existence and which will hereafter be constructed in line with the testimony of the witnesses who have testified on that point will be fully occupied and that rents will be paid throughout the remainder of the period. That is true with the exception of some bunk houses the rooms in which are not 100% occupied. All the houses are occupied.

The amount shown in column 3 is the total of columns 1 and 2, and the amount shown in column 4 is the average for the 23-year period. The total revenue is derived from the addition of the figures in lines 4, 5, and 6 in each one of the columns.

The amount shown in column 1 of line 8 was taken from Mr. Miller's Exhibit 138. The amount shown in column 2 was taken from the exhibits of the various superintendents who have testified and whose exhibits were summarized by Mr. Bussard in Exhibit 117. In addition to the figures taken from these Exhibits, it was necessary to add to those figures the amount of payments which will be made to
Canadian River Gas Company covering the payment
1040 for gasoline extracted from gas which they furnished
to Colorado Interstate for resale to us. That gas is treated at our Fritch gasoline plant.

Going back to line 5, captioned "Revenue from gasoline sales" it will be noted that Mr. G. M. Davidson's figures of gross revenue include all the gas which will be produced by that gasoline plant at Fritch and approximately ¼ of that gasoline comes from the gas produced on the Canadian River's reserves and purchased by us from Colorado Interstate Gas Company. I say approximately 25% because that figure varies slightly from month to month. In order to offset the inclusion of that amount of gasoline for which under contract we must account to the Canadian River, we have added that amount to the operating cost. Otherwise, we would be including in our revenue money that in fact goes to the Canadian River. I do not have with me the working papers showing how I arrived at the net amount which I added in there. It is among the underlying work sheets supporting this exhibit and it, together with all the other facts underlying this exhibit, will be available to the accountants of the two commissions if they desire to check my figures.

The amount shown in column 3 is the total of columns 1 and 2 and the amount shown in column 4 is the average for the total period of 23 years. You will note that in the next line we make a deduction in each one of the columns for "Company used gas" as shown by the word in parenthesis "Deduct". This is explained by the circumstances that the companies for their bookkeeping purposes to reflect the departmental operating cost make a charge to the departments for the gas each department uses. Since the cost of producing that gas is already in operating expenses in various forms, we deduct the charge made to the departments in the aggregate in order to avoid any duplication of charges. The amount shown in column 1 is taken from Mr. Miller's Exhibit 138. The amount shown in column 2 is taken from the departmental exhibits summarized in Exhibit 117. Column 3 is the total of columns 1 and 2 and column 4 is the average for the 23 year period.

In line 10, captioned "Maintenance Expense", the amount shown in column 1 is taken from Exhibit 138. The amount shown in column 2 was taken from the various exhibits of the department superintendents summarized in Exhibit 117 except that we have deducted from those expenses shown in those exhibits the expense of retiring property which we have set out here as a separate item. The two lines 10 and 11 constitute the same totals as those set out in the exhibit to which I have referred. The totals in column 3 and the average in column 4 were obtained in the same way as the other totals and the averages of this exhibit to which I have testified.

In the line captioned "Expense of retiring property" the amount shown in column 1 was taken from Exhibit 138, the amount shown in column 2 was taken from an analysis of the department superintendents' exhibit, summarized in Exhibit 117, and represents the cost of retiring the property to be replaced. The amount shown in column 3 is the total of columns 1 and 2 and the amount shown in column 4 is the average for the 23-year period.

The figures in line 12, captioned "Maintenance contingencies (10 per cent)" are based on the testimony of several witnesses. In the testimony of Mr. Kesinger, Mr. G. M. Davidson and the departmental superintendents, they stated that the maintenance items included in their exhibits which were summarized in Exhibit 117 were the minimum maintenance expenses that they would foresee at this 1041 time but they did not allow for unforeseen or contingent items. In Mr. Biddison's testimony in respect to the maintenance exhibits of the various departments, he stated that in his opinion, the figures reflected by the department heads should be increased at least 10% to cover the unforeseen items that always occur. On the basis of the testimony of these various men, I have provided in this Exhibit an item of maintenance contingencies of 10% which is 10% of the amount shown for maintenance expenses and the expense of retiring property shown in lines 10 and 11. Through this procedure, I arrived at the amount shown in column 2 which is the same amount reflected in column 3 and column 4 reflects the 23-year average.

The figures represented in line 13, captioned "Net operation, maintenance and retirement expense" are the sum of the amounts reflected in lines 8, 10, 11, and 12, less the amount shown in line 9.

The figures shown in line 14, captioned "Revenue remaining for amortization and return" were obtained by deducting from the amount shown in line 7 the amount shown in line 13. The amount shown in column 1 of line 15, captioned "Capital expenditure excluding cost of gas reserves" is the aggregate capital expenditure to date including replacements but deducting any salvage obtained from the materials reclaimed as obtained from analysis of the books and records. The amount shown in column 2 was taken from exhibits of the various departmental superintendants on future capital expenditures and replacements as summarized in Exhibit 117. The amount shown in column 3 is the total of columns 1 and 2.

In the testimony of Mr. Kesinger, Mr. G. M. Davidson and the departmental superintendents, they stated that the items of replacement as reflected in their exhibits were only those that they could foresee at this time and did not include any unforeseen items or contingent items. In Mr. Biddison's testimony with respect to the items of replacement, he stated in his opinion that the amount provided for replacements in the various exhibits of the departmental superintendents should be increased by at least 10% to cover unforeseen and contingent items.

On the basis of the testimony of these men, I have included an item for replacement contingencies of 10%, that is 10% of the total cost of replacements as obtained from an analysis of the exhibits of the various department superintendents after deducting the current salvage obtained from the retirement of the property replaced. These are the figures set out in line 16 under the caption "Replacement contingencies."

The figures shown in column 1 of line 17 under the caption "Cost of gas reserves" was taken from Exhibit 138 prepared by Mr. Miller. The amount shown in column 2 totaling $2,800 is an expenditure which has been made during the first part of 1939 and is reflected on the books. The amount shown in column 3 is the total of the amount shown in columns 1 and 2.

In line 18, captioned "Working capital" the figure $975,000 was taken from the testimony of Mr. Eastman and from Exhibit 125. That figure is applicable from the beginning of operations and is not repeated in the second column. We did not add to the working capital from year to year, since this figure does not change.

The figures shown in line 19 under the caption "To-
1042 tal capital expenditure and working capital" are the
totals of the figures shown in lines 15, 16, 17, and 18 for the first three columns. The fourth figure, $71,777,589, is the average of the yearly averages. That is obtained by taking the sum of the capital expenditures and working capital at the beginning and end of each year, dividing that sum by 2 each year throughout the period and adding together the 23 yearly averages, dividing that sum by 23, which gives the average yearly average.

The figures set forth in lines 21, 22, 23, and 24 under the sub-caption "liquidating salvage value" were taken from Exhibit 122 as corrected by Exhibit 124. That exhibit was explained by Mr. G. M. Davidson. The amount shown in line 23, entitled "Working capital cash," is the total cash used by Mr. Eastman in the computation of his working capital. We have reflected it as salvage at full value. The amount shown in line 24 is the total of lines 21, 22, and 23.

Question by the Examiner.

I have included in line 18 working capital, which is made up of cash, material, and supplies and other items. You will note in line 22 we show the salvage of the warehouse materials. We reflected the cash in line 23.

Direct Examination by Mr. Morgan Resumed.

The total in line 25, captioned "Total Capital Expenditures and working capital, less total liquidating salvage value (total amortization) $78,284,009," is the difference between the amounts shown in column 3, line 19, and the amount shown in column 3, line 24.

The amount reflected in line 26, column 3, is the difference between the amount reflected in column 3, line 14, and the amount reflected in column 3, line 25. The amount shown in line 26, column 4, in the amount $4,589,790 is the average of the amount shown in column 3 arrived at by dividing the amount in line 26 by 23. That gives the yearly average of the revenue remaining for return. The figure 6.39 shown in line 27, caption "Average rate of return" is determined by dividing the $4,589,790 shown in line 26, column 4, by $71,777,589, which is the average total capital expenditure and working capital shown in line 19, column 4.

On page 2, the first column is the same as column 1 from lines 1 to 19 shown on page 1. The last two columns on the page are the same as columns 3 and 4 of page 1 to and including line 19. The lines in between are merely the break-down of these figures by years for the years 1939 to 1954, inclusive. That is the break-down of the figures shown in column 2 of page 1.

(EXHIBIT 140 was offered in evidence. Counsel for each of the Commissions stated objections to the admitting of this exhibit, and the Examiner reserved his ruling until the next session of the hearing.

At this point counsel handed the reporter a document captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company (Combined) Earnings Statement Based on Book Cost as of January 1, 1939," with the request that it be marked for identification. At the direction of the Examiner, such document was marked Exhibit 141.)

1043 I have before me Exhibit 141 which was prepared by me and under my direction. This exhibit is a combined earnings statement based on book cost as of January 1, 1939 of the defendants. By book cost I mean the actual cost as reflected in the books of the companies insofar as those costs have been entered down to January 1, 1939. The figures shown in column 2 of lines 1 to 10, inclusive, are the same figures shown in the same lines in column 2 of the same lines of Exhibit 140 and were derived from the same sources. Since this exhibit covers the earnings for 16 years, the amounts reflected in lines 1 to 10 inclusive of column 3 are obtained by dividing the amounts in column 2 by 16. This 16-year period extends from January 1, 1939 through the year 1954. The basis for the figure in column 2 of line 11 is the same as stated in connection with the item "Maintenance contingencies" in exhibit 140 and is 10% of the amount reflected in line 10. The figures shown in column 3, line 11 were obtained by dividing the amount shown in column 2 by 16. The amount shown in column 2, line 11 of this exhibit differs from that shown in column 2, line 12 of Exhibit 140 for the reason that included in the maintenance contingency in Exhibit 140 was 10% of the cost of retiring property. In this exhibit, the cost of retiring property has been classified under reserves for replacements and is shown in line 15; and the 10% contingencies on this item is included in line 17 and has been omitted from the contingent item in line 11.

Line 12 is the sum of lines 8, 10, and 11, less the figure shown in line 9. The figures shown in columns 2 and 3, line 13, captioned "Revenue remaining for replacement, amortization and return" represent the difference between the amounts shown in the two columns in line 7 and the amounts shown in the two columns in line 12.

The figures $3,105,244 and the average figure $194,078 were obtained from an analysis of Exhibit 117. The latter figure is the result of dividing the former figure by 16.

The figure $109,449 shown in line 16, cost of retiring capital replaced was obtained from an analysis of Exhibit 117 and the amount shown in column 4 is the 16 year average. It is the same figure shown in column 2, line 11 of Exhibit 140.

The amount $541,253 shown in line 16 under the caption "Salvage value of retirement (deduct)" was taken from an analysis of Exhibit 117. The amount shown in column 3 is the 16-year average. This item, salvage value of retirements, does not refer to the liquidating salvage value which was the subject of Exhibit 122 entered by the testimony of the witnesses, G. M. Davidson, Taubman, Solow and Smith, but the salvage realized when the material is placed in stock for future use or which is used in construction work in progress or trade in for costs of part of new material, such as automobiles, mechanical office equipment, and so forth. When this material is carried into other work, or other equipment, or into the warehouse it is retired at its original cost.

The item under the caption "Replacement contingencies (10 per cent)" was obtained on the same basis that the replacement contingencies were determined in Exhibit 140, except that the item shown in line 17 in Exhibit 141 is 10%
of the amount shown in lines 14 and 15 column 2,
1044 less the amount shown in line 16. The totals in column
2, line 16 were taken from an analysis of Exhibit 117.

The totals shown in line 18 are the sums of the amounts shown in lines 14, 15, and 17, minus the amount shown in line 16.

The figure $49,830,479 shown in line 18 under the caption "Capital expenditures per books, excluding gas reserves" was taken directly from Exhibit 138 submitted by Mr. Miller. The figure $2,485,079 shown in line 20 under the caption "Viewed depreciation (deduct)" is the amount which represents the viewed depreciation shown in Exhibit 125 adjusted to the amounts shown by the companies' books by accounts. There are quite a number of computations involved in these adjustments, because we had, in Exhibit 125, to spread back the overheads by accounts and then arrive at a per cent depreciation which we applied to the amounts in the corresponding accounts on our books. This amounts to a percentage relationship derived from Exhibit 125 applied to the accounts as stated on the books. The steps we took and the figures we used in arriving at this figure are among the underlying work sheets supporting this exhibit and will be available for inspection and checking.

The figure $12,402,884 shown in line 21, captioned "Cost of gas reserves, less depletion to January 1, 1939" is arrived at by computation based on the total cost of the companies' gas reserves to date less any salvage realized as reflected by the books. That amount is multiplied by a factor which is the ratio of the recoverable reserves at 25 pounds abandonment pressure under the leases of Texoma as of January 1, 1939 shown by Exhibit 28 and supporting testimony and the amounts recoverable at 25 pounds abandonment pressure under the same leases on August 1, 1931, which was the date Texoma acquired its leases. The ratio of these two numbers is the factor used to multiply by the total book cost to date to arrive at the figure of $12,402,884 shown in column 1. By book costs in this connection, I mean the actual cost of the leases as reflected by the books.

The deduction for depletion is not the same figure reflected on the books of the company for the item "Depletion of reserves." The company books reflect depletion based only on the gas taken out of the leases by the company, while this figure is based on all gas that has passed out or from under the leases between August 1, 1931, and January 1, 1939 inclusive. In other words, in this exhibit we have depleted the leases not merely by the quantity of gas which Texoma has produced from the leases but by the total quantity of gas which has moved out from under those reserves between the two dates last above mentioned both by production and by drainage to other wells.

The figure $9,338,983 reflected in column 2 of line 22, captioned, "Cost of additional property" was taken from the exhibits of the departmental superintendents covering additional capital expenditures in the future, which were summarized in Exhibit 117. That is, the total additional capital expenditures reflected by those exhibits less the amounts which will be paid out for replacements. This represents property in addition to that which we held on January 1, 1939. It does not include any replacements.

The figure shown in line 23, captioned "Going concern value" was taken from the testimony of Mr. Hamilton and "Working capital" shown in line 24 was taken from the testimony of Mr. Eastman and is reflected in Exhibit
1045 125. Mr. Emery also testified on the subject of going
concern value. I do not have the exact figure in mind, but it was slightly in excess of the $8,500,000 shown in this exhibit. I took the lower figure in this computation. The total shown in line 25, column 1, is the sum of the amounts shown in lines 19, 21, 23, and 24, less the amount shown in line 20. The total shown in column 2 of the same line is the sum of the total shown in column 1 and the amount shown in column 2, line 22, which gives a total of $78,562,267. The amount last stated is the total capital employed in the course of the 16-year period.

In line 26, we have the caption "Total rate base," which is an average figure and is the average of the 16 yearly averages amounting to $75,305,459. The figures liquidating salvage shown in lines 28, 29, 30, and 31 are the same figures as those reflected in lines 21, 22, 23, and 24 of Exhibit 140 and were obtained from the same sources. The total, $77,513,135, shown in line 32, under the caption "Total to be amortized" is the difference between the total shown in column 2, line 25, and the total shown in column 2, line 31.

The amount shown in column 2, line 33, $69,960,256, is the amount if set aside in 16 equal annual amounts of $4,372,516, the amount shown in column 3, beginning December 31, 1939, with interest compounded annually at the rate of 1.35% would equal by the end of 1954 $77,513,135, the total shown in column 2, line 32.

The total shown in column 2, line 34, is the total shown in line 13, column 2, less the totals shown in columns 2, line 18, and line 33. The amount shown in column 3 of line 34, is the yearly average of the amount reflected in column 2. The figure 4.79% shown in line 35 under the caption "Rate of return" was determined by dividing the amount shown in column 3, line 34, $3,603,964, by the amount shown in column 3, line 26, entitled "Total rate base" or $75,305,459. The result of this division gives the percentage of 4.79%, which is the average rate of return based on the average annual revenues and the average capital employed.

The first column, page 2, is the same as column 1 on page 1 down to and including line 26. The last two columns are the same as columns 2 and 3 on page 1 to and including line 26, the other columns are the yearly break-down of column 2, page 1, for lines to and including line 26.

(EXHIBIT 141 was offered in evidence. Counsel for each of the commissions objected, and the Examiner deferred his ruling on the admissibility of the exhibit until the next session of the hearing.

At this point, counsel handed the reporter a document captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company (Combined) Earnings Statement Based on Reproduction Cost New, Less Existing Depreciation as of June 1, 1939," with the request that it be marked as an exhibit for identification. At the direction of the Examiner, such document was marked Exhibit 142.)

I have before me Exhibit 142. This exhibit was prepared
under my supervision and is a combined earnings
1046 statement of the two companies based on the reproduction
cost new, less existing depreciation as of June 1,
1939. By "reproduction cost new, less existing depreciation" I am referring to the reproduction cost new of the physical property as testified to by Mr. Hamilton and his associates and shown in Exhibit 125 and the viewed depre-

ciation as reflected in this same exhibit which is the depreciation prepared and testified to by Mr. Biddison. In other words, this is a computation based on the figures which speak for themselves in the exhibit, except that insofar as the value of the physical property is concerned we have used the figures which are arrived at by deducting viewed depreciation from the reproduction cost new of the properties owned and held by the companies as of June 1, 1939. The other figures contained in the exhibit are figures which are explained by the captions in the several lines opposite those figures.

It will be noted that this earnings statement is based on a period beginning June 1, 1939 and extending to December 31, 1954, or a period of 15 years and 7 months. The figures in columns 2 and 3, to and including line 18 were arrived at in the same manner as the figures for lines 1 to 18 inclusive shown in Exhibit 141 were adjusted so as to leave out the first 5 months of 1939 and the figures then represent the period of 15 years and 7 months. We took out the first 5 months of 1939 in this study instead of leaving them as we had in Exhibit 141 because in Mr. Hamilton's reproduction cost new study, he applied his study to the property of the companies as of June 1, 1939 and we did not attempt to apply this back to the beginning of the year. We started at the same time his valuation was effective.

The amount shown in column 1, lines 19 and 20, were taken from Exhibit 125. The amount shown in column 1, line 21, is the value of the gas reserves as testified to by Mr. Wallace. Those figures are based on Exhibit 131 which has been received in evidence. In connection with the testimony of Mr. Wallace, subject to some corrections in arithmetic, the figures here used are the uncorrected figures. When those errors in arithmetic in Exhibit 131 have been corrected, we will correct Exhibit 142 to conform to it.

The amount shown in column 2, line 22, after the caption "Cost of additional property" was taken from an analysis of the cost of additional property shown in Exhibit 117, with the property which was installed during the first 5 months of 1939 omitted, as these items were included in Mr. Hamilton's figures. The amount shown in column 1, line 23, "Going concern value" was taken from Mr. Hamilton's testimony and the amount shown in column 1 of line 24, entitled "Working Capital" was taken from Exhibit 125.

The total in column 1, line 25, is arrived at by adding the amount shown in lines 19, 21, 23, and 24 and deducting the amount shown in line 20. The total shown in column 2, line 25, is the sum of the total in line 25, column 1 and line 22, column 2. The amount $82,245,330 shown in line 26 after the caption "Total rate base" is the average of the yearly averages based on a period of 15 and 7/12 years. The figures in the next 5 columns under the caption "Liquidating salvage value" for "Capital expenditures," "Warehouse stocks," "Working capital cash," and "Total liquidating salvage value" shown in column 2, lines 28, 29, 30, and 31 are the same as those shown in lines 21, 22, 23, and 24 of Exhibit 140.

1047 The amount, $84,294,995, shown in line 32 as the total to be amortized, is the difference between the amount shown in column 2, line 25, and the amount shown in column 2, line 31.

The amount of $76,302,249 shown in column 2, line 33, after the caption "Amortization allowance" is the amount which, if set aside in 15 annual payments, each in the amount of $4,896,401, shown in column 3 of the same line, beginning June 1, 1939, and one additional payment at the end of 1954 equal to 7/12 of $4,896,401, together with an interest rate compounded annually at 1.35%, would by the end of 1954 equal $84,294,995, the total amount to be amortized as shown in column 2, line 32.

The amount shown in column 2, line 34, is the amount shown in line 13, column 2, less the amount shown in line 18, column 2, and line 33, column 2. The amount $3,031,987 shown in column 3, line 34, is the yearly average of the amount shown in column 2, same line.

The figure 3.69% shown in line 35 after the caption "Rate of return" results from dividing the total in column 3, line 34, by the total in column 3, line 26, of this Exhibit 142.

On page 2 of this exhibit, the first column is the same as column 1 on page 1 to and including line 25. The amount shown in the last two columns of this sheet are the same as columns 2 and 3 on page 1 to and including line 26. The second column on this page is a monthly average for the last 7 months of the year 1939. This represents just a monthly average for the last 7 months of 1939 and is not reflected on page 1. The figures shown in column 2 of page 2, Exhibit 142, are 7/12 of the amount shown in column 2 of the same page of Exhibit 141.

The other columns under the captions "1940" through "1954" respectively are the break-down into the yearly figures of the figures shown in column 2, page 1, lines 1 to 26 inclusive.

(EXHIBIT 142 was offered in evidence. Counsel for each of the Commissions objected, and the Examiner withheld his ruling on the admitting of this exhibit until the next session of the hearing.)

1048 (October 2, 1939.)

(Counsel presented the affidavits of Robert Ricks and others, all bound together in a document styled "Natural Gas Pipeline Company of America—Texoma Natural Gas Company. Affidavits of Appraisal of Lands in Fee and Rights of Way" with the request that they be marked as an exhibit. At the direction of the Examiner, the documents collectively were marked Exhibit 143 for identification. EXHIBIT 143 was offered in evidence. At the request of the counsel for the two Commissions, the Examiner announced that his ruling would go over until the following day.

At this point, counsel handed to the reporter the data furnished by witness G. M. Davidson, entitled "Natural Gasoline Production and Prices", with the request that the document be marked as an exhibit for identification. At the direction of the Examiner, the document was marked Exhibit 144 for identification. EXHIBIT 144 was offered in evidence. At the request of counsel for each of the Commissions, the Examiner deferred his ruling on admitting this exhibit until the following day.

Counsel then handed the reporter a document styled "Reconciliation of Statements Included in Exhibits 136 and 15", prepared by Mr. Miller at the request of the Examiner, with the request that it be marked as an exhibit for identification. The document referred to was at the direction of the Examiner marked Exhibit 145 for identification. EXHIBIT 145 was offered in evidence. At the request of counsel for each of the Commissions, the Examiner deferred his ruling on that exhibit until the following day.

At this point, counsel handed the reporter a 1-sheet document styled "Texoma Natural Gas Company, Summary of Market Value of Leases, By R. J. Wallace," explaining that it was a correction of the summary page of Exhibit 131. At the request of the Examiner, the document was marked Exhibit 146 for identification. EX-

HIBIT 146 was offered in evidence. At the request of counsel for the two Commissions, the Examiner deferred ruling on the offer until the following day.)

1049 ROBERT H. DELAFIELD, a witness for defendants, testified:

Direct Examination by Mr. Morgan.

(October 2, 1939.)

My name is Robert H. Delafield. I live at Hewlett, Long Island, New York. My place of business is at 61 Broadway, New York City.

I am vice president of the Columbia Gas & Electric Corporation, vice president and director of Columbia Engineering Corporation, a subsidiary management company, and a vice president of most of Columbia Gas & Electric Corporation's principal subsidiaries and a director of many of them. For some 17 years before I went to Columbia Gas & Electric Corporation in 1931 as a vice president I was employed in various capacities by the National City Bank of New York or the National City Company. Those capacities included early training as a statistician and securities salesman. I was subsequently managing director of the company's business in New England and a buyer of securities in New York.

I went with Columbia Gas & Electric Corporation as financial vice president in which capacity I have continued to date. My duties as financial vice president include the placing of securities for the purpose of raising funds for the companies of which I am an officer. Since going with the company I have personally negotiated the sale of all securities sold by Columbia or any of its subsidiaries, and I have also been in charge of setting up those securities. For 17 years, with the exception of time out for the last European war, my time was devoted wholly to the securities business. In the past eight years it has been an important part of my duties but only one of a variety of duties. I have had occasion in connection with my duties to inform myself concerning what is commonly referred to as the rate of return earned by corporations and the relation of that rate of return to the issuance and placing of securities for the purpose of raising capital.

As a securities buyer that is, of course, an important element in the consideration of the credit of any corporation. Since I have been connected with the utility business I have carried on and had carried on under me extensive studies into the subject of rate of return, both from the standpoint of the economics of our own business and also from the standpoint of appearances before regulatory commissions. I have testified before regulatory bodies on this subject. In connection with my testimony and in preparing myself to testify we made a great many intensive studies over a long period of years, and I should say that in the last nine years I have had at least two assistants who devoted a quarter or a third of their time to this particular subject. They worked under my direction. That study has involved the study of business and returns and profits on business not only in this country but in other countries, and not only in present and in recent years but in the past. We are not through with that investigation yet but we have done a great deal of work over a 9-year period.

Rate of return is the rent for capital. On the income statement there is gross corporate income, or income available for interest. That is the income that a company makes after the payment of all its operating expenses and after accruals for taxes, depreciation, amortization
1050 and similar charges. In other words, it is the amount of money that the provider of the capital obtains for permitting his capital to be used in any enterprise.

That includes all security holders. Bondholders, if there are any, preferred stockholders, if there are any, common stockholders, small creditors, bank lenders, and so on.

Particularly in extractive industries, as in the case of the natural gas business, where the business of the company is selling its assets, it is common, or not infrequent, to set up an amortization fund or reserve to return to the investors the amount of money that they used to purchase those assets. That is ~~not~~ rate of return or any part of rate of return. The investor in an extractive industry is entitled to receive the capital that he put in plus a proper return on that.

I would like to illustrate that, if I may, with the simple example. If a man bought a country grocery store, buying the stock of the store for say $2,000 and you do not allow amortization you would be saying to that man "You can run this business, you can make what profit you can on it, but at the end of the period when you wish to get out of business you must throw that $2,000 stock away, you are not allowed to get back the money which you paid for it." The natural gas business is exactly the same. You do not have grocery store stock but you have a stock of gas in the ground which you purchase and which you deliver with pipes instead of a delivery wagon. Those are the things you have in your business that you need to sell, your inventory of material, and each time you sell some of it you have less of it.

The amortization is a provision for the return of the capital to the investor. The rate of return may be distinguished from the return of the capital by referring to it as the return on the capital. The rate of return on any business or any investment is made up of two parts: first, is the fundamental section of the rate which is called "pure interest". That is the rate that any investor would receive if he were fortunate enough to make a riskless loan. The other part is what is known as a "risk premium", which is the amount in addition to pure interest that it is necessary to offer to the investor to attract or entice his money into any venture. Pure interest is a thing that at any one time is always the same. It may vary from time to time. Risk premium, however, not only varies from time to time but is different at any one time for a different type of risk.

Pure interest is the same for all borrowers of any kind or type. Now a given borrower at a given time might borrow at less than the pure interest rate by reason of some perculiar condition. As an example of that is a municipality borrowing on a tax exempt security. Tax exemption might force the rate on that security below the pure interest rate. Simultaneously a gas company might borrow money without tax exemption, with substantial risk, and while the factor of pure interest will be the same in the two investments the actual rate of return will be, of course, totally different.

I do not mean by pure interest the least rate of interest that is being paid by anybody as of a particular time. It is very difficult to put your finger on the exact 1/100 of 1 per cent of determination of what pure interest
1051 would be at any given time. There are a great
many measures. By applying many measures you

come to a judgment figure. It has been frequently done over a long period of years. Ordinarily, you would look to the yield on very high type securities, as, for example, Government bonds. Now you have frequently periods, as you have in my opinion in the last seven years, when Government bonds generally, for a multitude of factors, sell at much less than the pure interest rate. There are other factors in there.

During the past seven years I believe that we have been in a period of marked credit inflation that tends to raise the price of securities and consequently lower the yields. That would not affect the pure interest, the actual pure interest rate existing at that time, but it might affect the price at which securities were selling in a free and open market. Markets are sometimes supported. As in the case of Government bonds, some three weeks ago you had a short decline on news that affected the credit where immediately the risk premium was coming into play, but the market was supported and resultant prices do not give you a true index of pure interest or risk premium. There are perhaps better measures that you can apply. One that would give you a good index would be the investment of a very large and diversified fund. For example, last year, at the end of 1938, the savings banks in New York stated a total bond investment of somewhat over $2,350,000,000. That was a widely diversified investment, held by many banks in securities that had been purchased under the New York Savings Bank Law, which is a rigid law, supposed to prevent the investment of the savings banks in unduly risky securities. On that huge fund the return for the year 1938 was 2.87 per cent. Now that is probably a pretty good index of what pure interest was during the year 1938. The per cent I have stated was the gross return on the total bond investment account of all savings banks in New York State, and against that return, of course, was the cost of operating those savings banks. They had other assets too, real estate mortgages and what not, but against that earning would have to be assessed the cost of operating the fund.

There are a great many reasons that might affect the yield on a given security. I have used Government bonds as an example. There might be a variety of reasons at any one given time from the standpoint of financial institutions, banks, why the liquidity of Government securities would encourage investment at much less than the pure interest

rate at any given time. There are other advantages to banks, particularly banks that are members of the Federal Reserve system, in purchasing Government securities. The ability to immediately rediscount them gives them a value other than their investment value. This characteristic of liquidity applying to Government bonds would attract any other type of investor as well as banks. In situations confronting business and industry such as we have had in the past few years there has been more capital than there were uses to which to put it and the investor, as a matter of fact, had the option of allowing his money to lie idle or put it in something that would yield him some return until he could find a place where he was willing to put it and take his chances on a higher return. To such an investor it is desirable to have his money in a liquid investment such as a Government bond, so that the moment that the opportunity arose he could shift that capital from a temporary investment where he was just getting what return he could in the meantime and put it into the investment which he really desired at a return which was satisfactory to
1052 him. We have had a perfect example recently in the sharp, sudden decline not only in the market for Government bonds but in the market for all high grade bonds in general, that was synchronized with the declaration or the outbreak of war in Europe. I think the underlying reason for a sharp decline in the bond market was that American investors were freeing their capital, getting it into the form of money so they could reinvest in other undertakings, for example only, in the stocks of industries that they thought would be quickly benefited by war. These investors run to sell these bonds and at the same time other investors, like banks, try to get out and save themselves losses before the market breaks. Thus we had a cumulative effect that resulted in the breaking of bond prices.

Risk premium is the part of the total rate which compensate an investor for the risk that he runs in any given investment. I think it may clarify it if I remind you that the rate on short term money is always less at a given moment than the rate on long term money. This is a simple example. The reason is that the average investor has a better idea of what is going to happen in the immediate future than he has as to the distant future. The risks of making a long term investment are greater than the risks of making a short term investment. If a given company went to the public at a given moment and asked for a six months' loan and a 20-year loan we all know from experience that the rate on the 20-year loan would be higher. That is the public's appraisal of the added risk in that long period.

There are other risks involved than the time element in making investments. Each industry has risks of its own which are peculiar to it, and there are some risks that are common to all industry. I should say it is never possible to figure out the exact per cent that would compensate for given risks although it is, of course, possible to figure out what measure the public will put on that risk. The price of a security in the market, if it is selling in the open market, is made by a great many buyers voting with their dollars to buy or sell, and it is that expression of opinion which is absolute and final that shows you what compensation they desire for particular risks. When you are trained in the pricing of securities and the analysis of these risks, and of that opinion on prices, as expressed by the public in their buying and selling, you can appraise the amount of risk premium that is required for a given risk to attract capital to it.

At any one moment if the Natural Gas Pipeline Company of America wants to finance, it would have to finance in the market in competition with not only all other people who wanted to finance at that particular moment, but all other people who had securities outstanding at that moment. For example, if this company offered its stock at a price which compared, on a risk premium basis, unfavorably with the stock of General Motors, or American Can, or some other undertaking, it would be almost if not entirely impossible to dispose of that stock. Economically, you cannot sell the same commodity in the same market at two prices at the same time. When you are selling credit you are merely selling it as you would butter.

Even a moderately informed investor if he were considering the purchasing of securities of a natural gas pipeline and producing company, would look around to see what other securities could be had for and the
1053 returns on those other securities. In fact we have a most complicated machinery set up to prevent the investor from looking at just one thing when he makes an investment.

That is one of the important elements in the Securities Act of 1933 which is administered by the Securities and

Exchange Commission. The whole purpose of that Act is to inform the public as to investments and prevent them from looking only at one thing and thus being uninformed.

In addition to the information available through the administration of that Act, the investor ordinarily undertakes to inform himself concerning opportunities in securities in general when he is contemplating the purchase of a security. Without exaggeration, having personally sold millions and hundreds of millions of dollars worth of securities, I know from experience that in practically every sale I have ever made when price became the final consideration, the investor, no matter who he was, always looked at price on a comparative basis and compared it with the price of other securities.

I have made studies of the rates of return on various businesses in the Chicago district.

(At that point counsel handed the reporter a document captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Data Concerning Rate of Return, Witness R. H. Delafield" with the request that it be marked for identification. At the direction of the Examiner the document was marked Exhibit 147 for identification.)

Exhibit 147 is a list of 128 companies, each one of which has some type of securities listed on the Chicago Stock Exchange. It includes all of the companies with securities listed on the stock exchange except regulated companies, finance companies, and companies actually in bankruptcy or receivership. In other words, it is, as far as we can make it, a complete list of those companies whose securities are listed or traded in on the Chicago Stock Exchange, which companies are not under regulation, with the two exceptions of finance companies and companies in bankruptcy. It includes not only profitable companies, but companies which in some of the three years shown, that is 1936, 1937, and 1938, operated at a loss.

The exhibit is set up to show in the left hand column the name of the company, in the second column the general description of the business, the third column the location of the principal plant or plants of the company, and then in three successive columns, each with three sub-columns the total invested capital as at the end of each of the years 1936, 1937, and 1938, the net earnings before interest, which the rate of return, and the relationship of those earnings before interest to the invested capital, which is the rate of return expressed in per cent.

In submitting this exhibit, I point out that there is no intent to compare the risk involved in any particular one of these undertakings with the risk involved in the business of defendants. The purpose is simply to show what rates of return were made by business in general and by successful business in the general area and region where these companies operate, or in markets where they would have had to compete for capital had it been financed in this period. That list covers the first three pages of the exhibit.

1054 This rate of return shown in the column under the caption "Rate of Return, percentage" represents the rate available for interest and dividends after all charges such as depreciation and other charges comparable to amortization and operating and maintenance costs, taxes, and things of that kind are paid. There are a large number of companies here and it is conceivable that one company or another company might keep its books in a way that would keep those factors out, but most of them do not. We have examined their statements and the net earnings before interest are supposed to be after all charges, cost of doing business, and accruals. Of course, the percentage figure would relate that to the capital investment, which is the sum of the capital of all kinds and the surplus, less net of depreciation reserves, where reserves are on the books. Net of depreciation reserves means just the capital involved in the business. The reason that it is net is because it gives you, as nearly as possible, the best index on the book figure that you can reach. That is the net sum of the capital on the liability side of the sheet and the surplus.

I took the particular three years shown in this exhibit instead of taking one year and making that the basis of the study because in the business life of a country there are cycles which affect all business, and to pick one year might very well give an improper index of the earning capacity of business as a whole. I think that is exemplified in the fact that the average rate of return for these 128 companies in 1936 was 9.3 per cent. In 1937 it was 8.37 per cent. Now we know that 1938 was a year of marked business recession and in that year the return was 4.37 per cent. The average for the three years on all companies—and this is a weighted average, in other words, the capital is multiplied by the earnings, so to speak, and then divided into it—the average for the three years is 7.32 per cent. I just add the capital and earnings all up and then divide. I should have explained that each one of these average rates, when you come out at the end, may be either cast up from the mean or cast down from the mean. In this instance it is cast down very heavily, because there is one very large industry, the packing industry, which has not been particularly prosperous in recent years. That is a large capital industry and consequently if it fell below the middle it would tend to draw the whole average down. On page 3 of this exhibit you will notice that Armour & Company, with a capital of almost $300,000,000, had an average return of only 3.63 per cent during that period. That would tend to draw the whole average down.

The red figures on page 3 indicate losses for those particular companies in any of those years. Now if you were to use this 7.32% as a measure for regulatory purposes obviously you could not regulate to loss or to destruction. If you drop out the red companies and use the black companies you come to an average of 7.48 per cent. That only eliminates those companies which show a red return in the average column at the extreme right side. A pipe line company desirous of placing its securities would not find itself in competition with those twelve companies who operated at a loss. They would not offer any competition in financing. This is also true of those others in the lower portion of the final column beginning with the company which offers only .39 of 1 per cent as a return on its investment. In reality I think that these defendants if in search of capital would be in competition with the successful companies of the group. You could eliminate a large number of those companies, let us say those that are less successful than the average. They would not be strong competitors for capital at any one moment. If we eliminate all those who made returns of less than 7.32 per cent on the investment we have left companies with an investment of somewhat over $924,000,000 making a return of somewhat over $108,000,000. (Objection by Commission Counsel to above testimony overruled.) That includes those companies
1055 which in the final column made 7.32 or above as a return, and 108 related to 924 is 11.73 per cent. That is to say those companies which earned as a return the average or more for the whole group actually earned

11.73 per cent on their investments. There ars 128 companies in all shown on this list. Those companies which made a return greater than the average numbered more than one-third of the total number of companies and practically one-half of the capital involved.

Columbia Gas & Electric Corporation, on a consolidated basis, that is including the subsidiaries, has a gross revenue of approximately $100,000,000 per annum. Of that approximately two-thirds arises from natural gas operations and a little less than one-third from electric operations; the small balance is from incidental businesses. There are two or three natural gas subsidiaries with a few shares of stock outstanding. Outside of those there are only two natural gas companies that have issues of securities like bonds or preferred stocks in the hands of the public. These are two natural gas companies each of which has an issue which was originally $6,000,000 and now somewhat less in the hands of investors. Each one of these two companies has assets of approximately $100,000,000. We finance the capital requirements of our other natural gas interests through the holding company instead of issuing the securities directly on the gas properties. There is a reason for this. The financial history of the natural gas business is not particularly fortunate, and natural gas companies as a class, do not generally have high credit, and their securities in the past have not been popular and readily salable to the public. When we finance through the holding company we are able to finance on a better basis because we have substantial electric earnings in addition to the gas earnings.

I spoke of two natural gas issues. Those were issues of $6,000,000, the par value of serial notes sold in 1934. They were sold privately to the Metropolitan Life Insurance Company and to the Mutual Life Insurance Company in New York, each taking a part of each issue. One was a loan to the Ohio Fuel Gas Company, the assets of which on the balance sheet were in the neighborhood of $120,000,000 and which earned interest on its notes about 14 times. The other was notes of the United Fuel Gas Company with book assets of approximately $85,000,000, which earned its interest, at the time the notes were sold, 14 or 15 times. The earnings have since improved. When those notes were sold to the insurance companies, with one exception, a life insurance company in New York had never bought a natural gas bond. Those were the first natural gas bonds they

bought. They bought those notes in January, 1934, on a 5½ per cent basis and insisted that Columbia Gas & Electric Corporation guarantee them, in order to get behind the credit of the operating subsidiaries, the credit of the parent with its electric business. That is an indication of the difficulty there was in the past in selling natural gas bonds. Both these companies have distributing facilities. There are two advantages in having distributing facilities that immediately occur to me. When you have an asset there that may not go entirely out of use with the complete extraction of your natural gas, that is one; the other is you have control of your market for the sale of natural gas, which is of vital importance. Since the sale of the two issues of $6,000,000 each of natural gas bonds in the year 1934 there has been marked change in the situation. The life insurance companies which in the past several years have been the largest single class of security buyers, have been substantial buyers of natural gas bonds. Just after those particular sales another company sold some natural gas bonds to the life insurance companies privately,
1056 and the life insurance companies which were then
seeking investments and had no natural gas bonds, proceeded to build up the natural gas sections of their portfolios and created a peculiar demand for the bonds of natural gas companies for the past four or five years when we have been in what we term an institutional market.

An institutional market is one in which the securities are sold to institutions rather than to private investors. Life insurance companies are the largest segment of the institutional market, and I might exemplify that by saying that unless you know in advance today that the large life insurance companies will buy an issue of this type, your sales problem becomes extremely difficult and almost impossible.

Coming back to the natural gas pipelines and production business for a few moments, we have classified this business as an extractive industry. It is a mining undertaking which is selling its assets to make earnings. Now not only is the natural gas business a mining undertaking at its production end, that is at its source of supply, but it is a regulated business at its distribution end in most instances, and it is therefore more risky than, for instance, a copper mine or gold mine, because not only have you the risk involved in the supply of any material that is under the ground, but you have a market at the other end the price of which is controlled in the first place, and which you cannot stop serving in the second place. If a copper mine were forced to sell because of economic conditions at prices which would not yield a profit, all you would have to do is shut down and leave a watchman. A gas company cannot quit business, and that is a very real risk.

From my personal relationship with buyers of securities I know that they have considered natural gas pipeline and production bonds risky. It is borne out by the ratings that natural gas bonds are given by the various statistical services, and it is also finally confirmed by the prices at which they sell. We have made a great many studies into that subject to see how the bonds of natural gas pipeline companies have been rated with reference to other securities. I have a list of those bonds which we have considered in the making of that study or used in the chart which we have made as a result of that study. On page 4 of my exhibit, 147, we compare the yield on securities over a period from the beginning of the year 1929 to the end of the year 1938, the yield on 15 high grade municipal bonds as published by Standard Statistics, 40 high grade public utility bonds as published by Moody, and 40 high grade industrial bonds as published by Moody, with 9 natural gas bonds which we have made up ourselves. The 9 natural gas bonds included at the end of this period were Cities Service Gas Pipeline Company 6's at 1943, North Central Gas Company 5½'s at 1955, Macon Gas Company 4½'s at 1952, El Paso Natural Gas Company 4½'s at 1951, Kansas City Gas Company 6's at 1942, North Penn Gas Company 5½'s at 1957, Oklahoma Natural Gas Company 4½'s at 1951, Panhandle Eastern Pipeline Company 4's at 1952, and Southern California Gas Company 4½'s at 1961. That is a selection of natural gas bonds which represents about the best that the industry has to offer. This study was not made for the purposes of this case. It is a study that we use for our own comparative purposes constantly in comparing the prices of natural gas bonds and I think reflects very fairly the investing public's appraisal of the comparative risks of those different types of securities.

1057 We use this study in other rate cases and we use it in pricing bonds ourselves. Of course it is kept up to date.

Beginning in the year 1929 and following the black line you will note that the yield on the natural gas bonds was throughout the year from 5.80 to as high as 6.40 per cent. At the same time 40 high grade industrials were selling to yield about 5.45 and 40 high grade utilities to yield about 5.25. The high grade municipals were down here at 4.25. Of course the primary reason for that is tax exemption. That is another factor that enters into their price. Now from the middle of 1931 to the end of 1934 these natural gas bonds sold at prices which at all times yielded more than 7 per cent. In other words, the senior securities of these natural gas companies, which are I believe entirely representative of the industry, the best that they had to offer, the most riskless security that they had to offer sold at the public's own price to yield the public more than 7 per cent on the investment. The comparison at the middle of 1934 is about 7.75 per cent for the natural gas bonds, about 5.25 per cent for the 40 utility bonds, about 4.45 per cent for the industrial bonds, and about 3.75 per cent for the municipal bonds. There are two very interesting points in this graph. You will note that at the beginning of the year 1933 the yields on utility bonds and yields on the industrial bonds cross, and from that time on the industrial bonds have sold on a more favorable basis than the utility bonds. You will also notice, so far as the natural gas bonds are concerned, beginning in the year 1934 there is a steady drawing together of the curves, indicating that the natural gas bonds sold on a more favorable basis in relation to the other bonds, and that I ascribe to the fact, to which I have just testified, that the large institutions who had never before been buyers of natural gas bonds stepped into the market and created for this period a peculiar demand for those securities.

The circumstance that early in the year 1933 the yields on the public utility bonds crossed the line of yields on the industrial bonds and became higher from that point forward through the year 1938 than the yields on industrial bonds is of significance. Of course I may be influenced by my interest and studies on this particular subject. I feel that it was just about that time, and just prior to that time, when the regulated rates of return of utility companies were very much reduced. In other words, we had been, generally speaking, in times of rate of return for utility companies of 7, 7½, 8 per cent, and so on—I mean electric companies, this group. Beginning about 1932 or 1933, there was a sharp cut in that as the result of a group of decisions which brought these returns down to 6½ or 6 per cent. Again I know from contact and relationship with professional investors like institutional buyers, that this

has been a cause of great concern to them. They had before them the example of the financing of the railroads operating on a legal rate of return fixed by law at 5¾ per cent, and the result of that, and I think that is the strongest influencing factor right at that period. In other words, it is my view, from my knowledge of the subject, that the change in the year 1933 from a situation in which public utility securities had theretofore sold at a lower yield and at a higher price than industrial securities to a situation where they began to sell for a higher yield and a consequent lower price is due to the pressure on the rates. You translate that into rates of return, because the rate of return in itself, I think, is one of the most important factors. It is pressure to reduce the earnings of the
1058 property which is immediately reflected in a decline
of their credit standing with the public. With very minor exceptions, almost all of the financing there since 1934 has been for refunding purposes. There have been some exceptions but very minor ones in relation to the whole. That indicates that there has been a retarding of the flow of new money into the industries whose securities have been negotiated as opposed to the conditions which obtained in prior years.

In its origin the natural gas industry was a by-product industry. There was a period of extremely rapid development during and just prior to the war years, that is 1913 and 1914. The biggest gas years I think in the history of the industry occurred in 1917 and 1918. At that time the natural gas companies were largely private undertakings, owned by groups of men, usually men who were in the oil business, because it was a by-product of the oil business, and subsequently, when natural gas began to stand independently on its own feet, which was in the middle 20's, it was only then that you could get the public, other than the public who were interested in and intimate with the oil business, to put money in any large volume into the natural gas business. There were, of course, exceptions. I can remember for many years the only natural gas bonds that I ever heard of were the Kansas City Gas 6's. As far as I was concerned, dealing in the general market of securities, there were no others. There were a few others which were traded occasionally in Pittsburgh and Cleveland, but in big markets they were never heard of. People did not deal in natural gas bonds.

Of the 9 companies which I have used here in this chart

on page 4, seven are either solely distribution companies or have important distribution facilities. Two exceptions are the Cities Service Pipeline Company which is a transmission system and Panhandle Eastern Pipe Line Company which is essentially a producer and transmitter although it has small distribution facilities. There are only 7 of these companies which, at the end of 1938, we could get complete figures on, and the combined capital ratio of those 7 was 42 per cent bonds, 20 per cent preferred stock and 38 per cent common stock. I have stated that to be the nearest per cent. I have investigated the earnings in relation to the interest requirements of the interest-bearing securities of these seven companies. We found that using the composite picture of those seven companies, that their bond interest was earned three times, that their bond interest and preferred stock dividend requirements on an overall basis was earned twice. That indicates to me that the public's requirements for the ratios on natural gas securities are inclined to be more rigid than they are for some other types of securities, notably electric securities. I have not made a specific study, but speaking as a generality, if a sound and successful electric company earned all its interest charges twice, or a little better than twice it has a pretty good credit. If it earns its interest charges and preferred dividends overall 1.6 or 1.7 times the preferred stock I think would sell at good prices. Now, I have not made a specific study of that. Those are judgment figures just from experience, in dealing with electric utility issues. It is quite common, for example, in dealing with electric company mortgages, to put a qualification in that bonds may be issued for 66 per cent of the cost of new property, provided that all interest is earned twice. I have never been able to get that kind of a provision in a natural gas mortgage. Had those earnings been less than three times the earnings on the bond issues I think the bonds would have sold at lower prices and at higher
1059 yields. That would have been true also with reference to the preferred stock. Based on my knowledge of the natural gas business and my experience in the handling of securities of all kinds, including those of natural gas companies, I doubt if that sort of return, 3 times the interest on the bonded indebtedness, amounting to an average of 42 per cent of the whole capital, and twice the combined interest on the bonds and preferred stock aggregating 62 per cent, would have been an adequate return to

sell the common stock at par, had it been necessary to finance the amount that went into the common stock also. We are thinking here in terms of bonds that are selling in the market all the time in small lots, and preferred stock selling in small lots, 5, 10, 20, or what have you. Now those securities are entirely different than securities involved when you go out and sell a new issue. Even with your own bonds, if you have a company and its bonds are selling, for example, at 100, and you issue additional bonds under the identical mortgage for added property which will add to earnings, you do not get the same price as for the bonds that are selling in the market. You get less. So what I mean by talking about minima is I am exaggerating here against new financing. I do not think you can necessarily go out and sell bonds at par on a 4½ per cent basis and sell preferred stock on a 6 per cent basis and then sell the common stock at such ratios as I have discussed. I do not think it would happen that way. . .

The natural gas business being an extractive industry, the buyers, whether they be bankers or institutions, always want to be sure that there is a margin of safety beyond the maturity of their obligation in the available supply of gas. For example, if you can satisfy them that you have a 25-year supply of gas they will not lend you money for 25 years; they will lend you money perhaps for 20. As you come down, if you can satisfy them you have a 15-year supply of gas they might, if they are extremely hungry, lend you money for 12 years, but usually with a very heavy sinking fund. A skillful and careful buyer would only lend you money for 10 years. By "heavy sinking fund" I mean it is quite customary in natural gas bond issues to have a 100 per cent sinking fund. If you will look again at this chart, that fact distorts the yield on natural gas bonds, as shown by this curve downward. By that I mean the Panhandle Eastern Pipe Line Company has an issue of bonds outstanding which will mature in 1952, so that the yield as used in this is taken to 1952. As a matter of fact, those bonds have a 100 per cent sinking fund so that their maturity is almost half way to 1952, and if this were taken into account the yield would be much higher. In other words, the money is being accumulated against the bonds in what is called a sinking fund for the purpose of protecting the owner against having to look to the resources as of the time the bonds mature.

Based on my knowledge acquired in dealing with the marketing of securities of all kinds and my knowledge of the natural gas business as an officer of the Columbia Gas & Electric Company, handling its securities as its vice president in charge of financial problems and in the light of all my knowledge concerning the attitude of the public towards the hazards and risks involved in the business of a natural gas pipeline producing company, I have an opinion as to what is a necessary and required return for a natural gas pipeline and producing company. I am familiar in a general way with the two companies involved in this proceeding. I know where their properties are and where their source of supply is. I know
1060 of course about the Panhandle of Texas gas field, its extent and its distance from Chicago, where these pipelines find most of their market. I have an opinion as to the necessary rate of return or the required rate of return to which these companies are entitled. I prefer, if I may, to answer that question by stating what I consider the minimum rate of return. I do not think that the Natural Gas Pipeline Company of America can continue to exist and finance and maintain its credit and raise the necessary money in the future for the additions it is going to have to have to do its business on a return of less than 8 per cent. Now, I am being very careful not to testify that that is a fair return, because in this type of extractive industry, after all the study that we have done, I am convinced that it is not. I think this type of industry is entitled to and should have for the future benefit of the investors in the company and for assurance of continuity of supply for the customers, a more adequate return on the necessary capital. In referring to rate of return I am relating the earnings to the rate base. I am not interested in the amount of the rate base, the dollars involved, or anything like that. It is simply a percentage relationship, the rate base to the amount that has to be paid to raise that capital.

I am familiar with the use of the term sinking fund as I have used that expression here. I am familiar with the practice among regulated concerns and regulating bodies of setting up and requiring from the standpoint of the regulating body, that reserves be set up for the return of the capital, either to offset depreciation as in the case of a utility which is continuing on, or for the purpose of returning capital in the case of a project like a natural gas producing company, which has a terminable life, so as to distribute the amount evenly by annual installments over the prospective life of the project, or for the life of the physical property as in the case of a utility. There are various methods of creating those funds. You refer to either a straight line method where a given sum is periodically deposited, designed to accumulate a final fund, or a sinking fund method where the amount is periodically deposited, which with interest and with interest on interest, creates a sum at a certain year. The purpose of an amortization fund, particularly in an extractive industry, is to return the capital to the investor, get his money back for him. If you wait until the last year, the business is over, there is no more, and to protect him you have to assure him by annual or periodic payments throughout the life of the business. That, incidentally, distributes the burden of returning the capital among all of the companies' customers from now until the project has reached the end of its life. Now if that fund is to be accumulated by the straight line method it is a simple matter of dividing the total amount to be returned by the number of years during which it must be accumulated. If it is to be accumulated by sinking fund accrual, you would set up a lesser annual sum than you would on a straight line basis, and then you would fix a rate of interest which you are sure you can get on that sum for the whole period for the life of the fund, and at the end of each period you reinvest the return on the fund itself, and do that each time, and for a small annual accretion therefore you build up the larger sum at the end. In other words, you make a smaller annual deposit but by putting your annual deposit to work, you do not have to put up so much out of the property itself. To state it differently, the amounts set up under the sinking fund are such amounts as, together with the interest and the interest on the interest, will amount to the total sum to be returned at the end of the project's life.

1061 From the standpoint of the investor and the standpoint of the company which owes the investor the duty to return that capital by the end of the project's life, an interest rate which is so low that you can be absolutely sure of getting it must be used in accumulating that fund by the sinking fund method. The only way to build up a sinking fund is to put a rate on it that you can be just as certain as it is humanly possible to be certain will never be broken. I believe that the biggest amortizers of funds like this are the life insurance companies. Life insurance companies use in New York 3 per cent, but that 3 per cent is not quite a true figure, because they are using for their mortality tables the 1885 American tables, and they have shortened the present span of life and therefore very much diminished the risk. As a practical matter I would not want to use 3 per cent, because I do not believe I could feel sure, over 15 or 20 years, of getting 3 per cent on every investment. I would much prefer and I would at this moment be more apt to pick a rate of 2 per cent which, I think, is a logical rate under existing conditions. That is a judgment figure, but it is a figure I would pick today if I had to accumulate a certain fund, to be sure of doing it. I would not go out and buy stocks with this kind of fund if you get 7 or 8 or 10 per cent return on stocks for the risk of losing your principal. That is why you get it. According to the previous testimony, I say you could not do that. You have to find the nearest to a riskless investment that you can find for a sinking fund or amortization fund. The company accumulating such a fund must avoid every possible risk, from the practical standpoint, and mathematically it is essential that they avoid risk and pick a low enough rate so that the very functioning of the interest on which they are relying to accumulate the fund can operate.

Cross-Examination by Mr. Slaff.

As to whether or not I would compound that interest annually, semi-annually, or quarter-annually, in figuring the 2% ordinarily you can compound semi-annually, simply because the fund is usually invested in bonds, and most bonds pay their coupons semi-annually.

Prior to my coming with Columbia and subsidiary companies I never testified in a rate case. Since that time I have appeared in rate proceedings before various commissions, I appeared before the Illinois Commerce Commission in 1932, testifying for another company. It was, I think, the case of the Central Illinois Light, having to do with the gas rate at Springfield. I have appeared before the Ohio Commission in cases involving the Ohio

Fuel Gas Company, the United States Fuel Gas Company, Cincinnati Gas & Electric Company, as far as rates are concerned, and I have appeared before that commission frequently for various companies in connection with matters of financing. I have appeared before the Pennsylvania Commission in a rate case for the Union Heat & Light Company, I should say in about 1933 or 1934. I have appeared before the West Virginia Commission in rate cases involving the Natural Gas Company of West Virginia, the Cumberland and Allegheny Gas Company, and in matters of finance involving the United Fuel Gas Company. I appeared, I think by deposition, before the Virginia Commission in matters, I think, involving service company contracts and financing. I am not positive whether that was a deposition or simply an interrogation. I made several appearances before the Ohio Commission in the Ohio Fuel Gas cases. I should say I appeared before that Commission in 1933 and 1934, and again
1062 in 1937. These proceedings involved the same municipality but they were different cases. All involved gas rates. In each one of those Columbus cases the United Fuel is brought in as the supplying company, and I appeared for it in those cases. I appeared in no other cases involving the United Fuel before the Ohio Commission, so far as I remember.

The Cincinnati Gas & Electric Company case was a gas rate case which was settled. It was tried, I believe, in 1934 and I appeared for it in that case. Now that, of course, would also involve an appearance for the United Fuel. I appeared as a voluntary witness in the Union Heat & Light case before the Pennsylvania Commission in 1933 or 1934. It involved gas rates. The Natural Gas Company of West Virginia case was a gas case, and my appearance was in the year 1932. The municipality involved was the city of Wheeling. The Cumberland and Allegheny Gas Company case involved gas rates. I am sorry I do not remember the name of the town that is involved in that case. That was in 1937 or 1938, the latter year I think. I believe I testified on rate of return for the Cincinnati Gas & Electric Company in an electric case in 1933, which case in turn was settled. That would be before the Ohio Commission. In Ohio you are required to submit your testimony. I do not remember whether my testimony was just submitted or whether it was submitted and I appeared. In either case the testimony is there. The case was settled and withdrawn.

Cross-Examination by Mr. Booth.

I have stated that I believe the term rate of return has two specific aspects, namely, pure interest and risk premium. That was the conception of rate of return which I had when I expressed my opinion in response to the question of counsel for defendants. I said in direct testimony that a good measure of pure interest at the present time was the rate on the bonds held by all New York savings banks, which in 1938 was 2.87, and I should think that between 2¾ and 3 per cent of the eight per cent in that range would be pure interest and the balance risk premium. While that is one element in my conclusion as to an overall rate of return, I did not specifically allocate 2¾ or 3 per cent as the factor of pure interest and the remainder to risk premium. So that there may be no misunderstanding, may I say that if at that moment the pure interest rate had been 2½ instead of, say, 2¾, I might still have arrived at 8 per cent as the minmum return. The principal factors in my mind in arriving at 8 per cent were, first, the rate necessary to compete with other industries for capital, which I arrived at by the first part of the exhibit put in this morning; second, I arrived at that rate by calculation and experience as to the amount of return rate that this company would need to be able to finance in competition with other companies, knowing the terms on which other companies financed. I divided that into pure interest and risk premium because, this being a peculiarly risky business, risk premium is a very important factor in arriving at the rate of return, but I wouldn't necessarily have to divide them three and five, although those are approximately the figures that I did have in mind in coming to that conclusion—2¾ and 5¼, roughly. That is my own personal judgment of it. I have stated in my testimony that the interest rate in determining the amount of interest that should be applied computed in connection with the amortization fund should, in my opinion, be 2 per cent. That is an experience figure, and, as I said, the largest amortizers of large funds are the life insurance companies who have great experience in the amortization of 1063 risks, where they actually amortize the policy on a man's life. They use 3 per cent, but I know that there are factors of safety in there that if I was setting up a sinking fund to retire a given amount of money, I wouldn't have, and I reduced that to the amount which I have felt over a period of years I could be assured of getting from outside securities that I could buy, allowing for a slight factor of safety there. If I may give you a perfect example, in that fund you would have diversity. If you went through a period such as we have been in in the past five years, I might well buy underlying bonds of the Cincinnati Gas & Electric Company on a 2.9 basis, and I might well buy underlying bonds of the New York Edison Company on a 3¼ basis, but I would also have to have some Government bonds in there as a matter of security, and those would be on a less than 1 or 1¼ per cent basis. Now when you think of the kind of fund you would have to have, you could conservatively make an investment that you could be sure of yielding you 2 per cent, because it must yield you 2 per cent. The investment must be on as risk-free a basis as you can find. That would be the purpose in investing that fund. If I invested it in securities of the class just described, namely, a combination of Government, New York Edison and Cincinnati Gas & Electric, and perhaps some municipal bonds or telephone bonds of A.T.&T. subsidiaries, and securities of that class, I obviously would not have a risk-free investment, but that would be as risk-free as I could get. Some of those bonds in the next 20-year period may well default. There is no such security as a risk-free security. The Government securities are as nearly risk-free as you can get.

Questions by the Examiner.

I observed that the life insurance companies use 3 per cent, because that group of institutions is the most widely experienced group in amortization They use that figure. I think I explained in my direct testimony and again just now that I know the life insurance companies have certain safety factors that I wouldn't have. Therefore, I must take a lower rate. I am governed by the fact that, as just stated, I would have to have some Government bonds. That would tend to draw the rate down. I might have some telephone bonds which would push the rate up, but I would be afraid to average, to attempt to average more than 2 per cent on a fund the whole purpose of which was never to lose one payment of interest or one payment of principal.

Cross-Examination by Mr. Booth Resumed.

I had the contracts between defendants and Chicago District Pipeline Company available for study and did study them when I was preparing for this case some time ago. That was 18 months ago, however. I think I might be able to answer a specific question as I am generally familiar with that contract. I read those contracts to be familiar with them but I didn't attach to any specific part of the contract a specific risk and say this would add one-eighth of one per cent, or anything like that. To be perfectly specific in my answer, there isn't any one particular provision to which I attach special significance in arriving at my conclusion as to the fair rate of return for defendants. The big risk factor in this particular business is that it contracts for its retail market and doesn't control it itself, and putting it in a conversational way, it is consequently at the mercy of the seller of gas who is only interested in this company as a means of getting that material. It
1064 is in a very weak position where it can't set up a type of rate, for example, retail rate, which might encourage the type of business which this company might need at a given time. That is a great risk. What I mean to say is that the fact that the market was a contract market was an important element of risk to this company. I don't think that the company is in a very weak position, but this situation presents an important element of risk. I concluded that the business would be less risky if defendants owned the distribution. I am not trying to avoid your question; I am trying to answer it specifically. It isn't a matter of a contract or a provision in a contract. It is a fact. These companies do not control their market and that adds to the risk of their business. I repeat that there is no specific provision in the arrangements between defendants and the Chicago District Company to which I attach special significance in determining the rate of return for defendants. It is the fact that the market and the supply are divorced that bothers me. I don't care how they are divorced or what the arrangements of sale is. It is the basic fact. I don't have to look beyond that into the details of the arrangements; they might be good or bad, and these, as I remember them, didn't bother me at all. There was nothing in them that upset me. What does

bother me is that the man who produces his gas and carries it 900 miles can't make the terms of his sales at the other end, subject only to regulation.

I did not say that the 8 per cent would be a reasonable or fair rate of return at this time. I was very careful to testify that it was a minimum rate. A minimum rate is the least, the smallest rate that I think a company could live on. I have no doubt that you will look at testimony in recent cases, or other cases, and I have testified often to an 8 per cent rate of return to gas companies in different kinds of businesses, each time testifying that it was a minimum rate. Now I don't think the risks in those different types of companies are identical, and I don't think that the fair rate for this company might necessarily be 8 per cent. I do think that it could get by on it; if you considered the risks and weighed them very carefully you arrive each time at a rate that is so high that under regulation there just isn't any use proposing it. An 8 per cent return is the minimum on which these companies can live, in my opinion.

Further Cross-Examination by Mr. Slaff.

I am not concerned with the rate base; that is the business of other witnesses, but I mean 8 per cent on the allowed rate base. If you allow X as the rate base and that rate base is extremely low in proportion to cost or to reproduction cost new, or to some other yardstick that you would apply, it of course would have the same effect as an unduly low rate of return. If you allow a generous rate base and a rate base which I would consider would include elements that many regulatory bodies do not consider now, then I think that you should allow 8 per cent on that rate base.

Further Cross-Examination by Mr. Booth.

As to the peculiar risks of the business of defendants, in the first place, I have stated several times on direct that it is an extractive industry and there is the risk of exhaustion of gas perhaps prior to the estimates of the geologists. I said the risk that it might be exhausted prior to the estimates of the geologists. I have a book of some
500 natural gas circulars published between 1920 and
1065 1930, and a single reading of that book and an estimate of gas supplies will convince you that the risk of

exhaustion of supplies prior to the geologists' estimates is something that is foremost in the minds of all investors. I have made no studies, nor am I qualified to make any studies, with respect to the life of the Panhandle field, or to state that it will, in my judgment, expire earlier than the date to which witnesses have testified. But that isn't the question. The question is whether there is a risk that it may expire earlier, and I am qualified to state that there is a very strong risk that it may—that field or any other gas field. I consider that of some importance in arriving at my conclusion as to the 8 per cent fair rate of return for these companies. There are other risks. I consider the risk, for example, of this property being reduced in value and use by a possible discovery of gas near the markets. You may have been familiar with the fact that there has been some drilling in southern Illinois and some gas found there which might affect the value of this property adversely if developed into a big discovery of gas. There are some mechanical risks that we all face in the long distance transmission of gas. It is almost impossible not to have occasional blow-ups, occasional failure of machinery, accidents that occur, and the chance is multiplied in a sense by the length of the line. I don't know that there is a direct relationship but the risk increases as the line becomes longer.

I have already spoken about the contract market. Now from the standpoint of finance, and without being unnecessarily combative on the stand, there is a risk in the minds of investors now that arises from the fact that the status of regulation at the moment is not fixed. Investors don't know what they are facing from a regulatory standpoint and that risk assumes great importance in their minds. You seldom deal with a large investor who doesn't bring up this point that I made this morning of the reducing rate of return which they are convinced will put the utility companies out of business. That is a risk. Further reductions will have a bad effect on the credit of these companies, this company and all other companies.

You ask whether there might be or is a tendency for regulatory bodies to use as a rate base the investment or prudent investment or original cost in the properties, so as to assure the investor always a return upon the investment that has been made in the property, might be a counterbalancing factor entering into the rate of return. I think, at the expense of lengthening the record, I will illus-

trate what I mean. In a property with which I am familiar we have a building which we purchased in 1921 or 1922 from the telephone company. For that building we paid approximately $200,000, $5,000 a front foot. Immediately across the street within a week a building sold for $8,000 a front foot. We made a good buy. But that building cost the telephone company, twenty-one years earlier, when it was on the outskirts of the city, $15,000. If you follow the theory of original cost, that is original cost to the first user who dedicates the property to public service, you see what they would do to part of your rate base. That is particularly true in a natural gas company where a utility might buy acreage and develop it and if you buy it from them you don't get the advantage of that cost to you in your rate base. That is a very real risk. If the theory of original cost were to be applied to gas producing lands it might have a serious effect on the future of natural gas companies. The only state in which prudent investment is used is in Massachusetts, and I think that if prudent in-
vestment were carried out as it is there, it wouldn't
1066 have a very great effect, but there is a wide range of
interpretation of the prudent investment theory. I
do not consider it to be a counter-balancing factor.

There are two risks that apply particularly to this company, in increasing costs. The first risk of increasing costs is the increasing costs that might come from a period of inflation and would affect any utility company or any company with fixed rates, where the costs increase more rapidly than the price of the product. That applies to all companies. But there is a particular risk that applies to defendants which is the cost resulting from a diminishing supply of gas. If, for example, the geologists erred three years in their estimates of the gas supply available, costs would increase more rapidly toward the end of the period because it is more expensive to get gas out of a field at a low pressure, and that is a risk in this business. If they erred in the sense of arriving at a conclusion, namely that the life of the field would be somewhat longer than they actually testified to, that would be recompensed for, of course. Now there is another risk in the natural gas business that is peculiar to the natural gas companies, and that is that in recent years, especially since 1929, there has been a sharp contraction in the individual use of gas by residential consumers. I don't remember the figures for the country as a whole. In our own system with over a million customers, the per customer consumption has dropped from about 78,000 feet per annum to about 58,000 feet per annum. The residential load, of course, is the most valuable part of the load, and a drop in that is disproportionate in loss of revenue to a drop in the industrial load. That apparently is caused by a change in the mode of life of people. Also a factor in that is the greatly improved appliances of which we are very glad. That is a risk. Until we know the borders of that decline in the gas business it is a very real risk for any investor, and it is a particular risk for this company with its contractual market, because if they find their domestic load falling off, they can't immediately take steps to correct it which they could if they owned the market, and the purchaser of the gas who buys at a price hasn't the same interest in correcting that as the producer of the gas. He is in a little different position.

A very extensive investigation has been made by the American Gas Association in the communities where natural gas is sold to determine whether there has been a decline in the use of gas in those communities. That investigation was headed by my immediate assistant and of course I am familiar with it and have discussed it with him several times. I am familiar with the situation of this company and many others in this country. I haven't the faintest idea as to what the drop per customer has been in the communities served by defendants. I believe there has been a drop. I say that the gas industry as a whole has suffered a sharp drop in the domestic consumption of gas. In a given situation a company might not have suffered such a drop. Supposing this company hasn't, the fact that the industry is suffering that loss is a risk to this company because if it hasn't felt it yet it may feel it tomorrow and the investor has to consider that. I don't know, but I am perfectly certain that these companies have suffered a drop in customer consumption. I am not interested from the standpoint of this particular company, in whether or not it has had that drop yet. It is a characteristic of the industry. I can't quite truthfully say that I have made no special study of the market of this particular company or the companies which distribute its gas. Of course I studied them quite thoroughly when I started this investigation about two years ago. I completed it about 18 months ago. I haven't done any concentrated work on the subject during the last 18 months except to review the results. The conclusion I testified to is the same as 18 months ago.

1067 There are other risks I would like to speak of. One is the rising cost of regulation. I have already spoken of one phase of it and another is rising taxes, which we are all familiar with. The natural gas business is unlike any utility business that I know of from a competitive standpoint, because it is in direct competition with other commodities. I would exemplify that by saying it would be inconceivable to any of us here to remove these lights and substitute candles and kerosene oil lamps, but we are perfectly familiar with the fact that people shift in and out from gas furnaces and gas heaters to coal; kerosene oil is widely used as a medium for cooking and that is in competition with gas. There is a further competitive element, and that is even under the new Natural Gas Act there is direct competition with other gas companies, and where you simply supply a market and you haven't the distribution system, you only have to lay a pipe to the edge of that market, so to speak; you don't have to replace a distribution system. It isn't so difficult for a man to walk in and get a certificate of convenience and necessity and plunk a line into your market. That is a serious risk. You don't walk in and get a certificate of convenience and necessity by paying a dollar fee, of course, but you are familiar with the wording of the law, and I think there is one recent decision within two months that exemplifies that very well. I am talking about Section 3 of the Natural Gas Act of 1935. The Lea Bill. That is the section of the act which enjoins the Federal Power Commission to grant certificates of convenience and necessity to those offering lower prices.

These are the major factors that I have considered. I don't think there are others that I have given consideration to. In the direct testimony I have very carefully stated it wasn't my purpose in putting in this exhibit to make a direct comparison of risk between any one company here and this company, and then amplified that to say that, supposing a man has $128,000—there are 128 companies here—and invested $1,000 in each one of those, and had the choice of doing that or investing $128,000 in the pipeline company, obviously he would run the less risk by investing in the 128 companies. That is a little impractical, he wouldn't do that. I don't think I am in position to compare any one company with the risks of these companies; but the fact is that these companies and a large group of them, the group risk being comparable to the risks in these companies, afford investments at higher rates of return than the 8 per cent which I consider the minimum for these companies. If we take a group of them the diversity factor reduces the risk in any one company. It isn't my purpose in this exhibit to show that individually the risks of any company listed there are comparable with the business of defendant companies. The businesses of the companies listed are not comparable with those of defendants but the risk of these companies as a group is comparable to the risks of these defendants. Some may have comparable risks, but I haven't analyzed them from that standpoint, and I am not in a position to testify as to that point. I am not interested in it from that standpoint. I haven't analyzed the risks of any of these particular companies.

The lists of the companies which make up Moody's Index for 40 high-grade industrials and 40 high-grade public utilities and the Standard Statistics Index for 15 high-grade municipals, shown on page 4 of my exhibit, are
changing lists. I would have to send that list to you.
1068 I would have to send you a list for every week since
1929. It is all published in the front of the manuals, but I can have it typed for you if you wish. That will involve my supplying ten lists, each list to embrace about 95 companies.

I am not familiar with the amount of new money, if any, that is needed by defendants now or in the future. I don't know that they need any.

Further Cross-Examination by Mr. Slaff.

The figures for invested capital and net earnings before interest shown on my Exhibit 147 stated at the sum of $238,263,948 of invested capital for Sears, Roebuck & Company, we took from the balance sheet of that company as published in the manuals. It was either Moody's or Poor's manual. They are all the same. And we added on the liability side all of the outstanding stock, all of the debt, if any—Sears, Roebuck hadn't any—plus the surplus. Now that is just what this is. The slight increase you see as you go along there, I think, is just added surplus from year to year. By debt I do not mean long term debt only. There are instances when the companies have short term debt that is in a sense permanent capital. In these periods there are very few because this is not a borrowing period; and where we might have missed one, it wouldn't make a bit of difference. For instance, if there were under current liabilities, a maturing bond issue, we would include that as capital, but it is an effort to get the total invested capital in the business, whether arising through the sale of securities or through surplus.

We may have used annual reports in a few instances, but usually we use the manuals just because it is easier. The reserves are net. In other words, we don't add in the depreciation reserve on the books as a part of the capital. The net earnings before interest for which this company shows a figure of $31,088,939 is the gross income on the income account—the gross corporate income. The same method was pursued for all companies.

Redirect Examination by Mr. Morgan.

By gross income I mean the income that is left after depreciation and operation and maintenance and all taxes and charges of that character. That is income available for interest.

Questions by the Examiner.

I cannot recall exactly the rate of return to which I testified as proper in the various hearings at which I have appeared. Usually I testified, as I have testified this morning, to a minimum rate of return. I don't think it has always been 8 per cent. In the case of some distribution companies it might have been lower, but frankly the more I have studied it the more convinced I am that industry can't go on at as low a rate. Naturally, testifying as a witness for the companies I don't want to make requests I realize in the light of existing regulation are out of reason. I think it will not work. I think we are going to pay the penalty of regulation.

I did know the sinking fund provisions for the outstanding bonds of defendants. As I remember the sinking
1069 Fund provisions, the bonds are cancelled and killed as
the sinking fund is accrued, so there would be no problem of reinvesting the fund. On these nine natural gas companies for which I have an overall figure that 42 per cent of the capital was in bonds, 20 per cent preferred and 38 per cent common, I think I can get a breakdown of the seven companies of the nine that enter into those figures.

I think I read into the record this morning the interest rate on the bonds of those seven companies. For instance, starting with Cities Service Gas Pipeline Company 6's, 6 per cent is the interest rate. North Central is 5½.

I can give you the other bonds which entered into the natural gas bond yield curve if you would like to have them. That is the table headed "Index of Natural Gas Bond Yields." There are five columns; lefthand column Poors Rating; next, Bonds Included in Index since January 1, 1929; next, Due Date Interest, next, "Date In," and next "Date Out." The table follows:

INDEX OF NATURAL GAS BOND YIELDS

Poor's Rating	Bonds included in Index since January 1, 1929		In	Out
B**	Cities Service Gas Pipe Line Company	6/43	1-29	12-38
B*	Texas Cities Gas Company	5/48	1-29	2-38
B**	Dallas Gas Company	6/41	1-29	9-38
—	El Paso Natural Gas Company	6-1/2/43	1-29	4-36
A	Kansas City Gas Company	6/42	1-29	
—	Lone Star Gas Company	5/42	1-29	10-37
A	North Penn Gas Company	5-1/2/57	1-29	
—	Oklahoma Natural Gas Company	6/46	1-29	7-36
—	Southern California Gas Company	5/57	1-29	3-31
A**	Southern California Gas Company	4-1/2/61	4-31	
B**	El Paso Natural Gas Company	4-1/2/51	5-36	12-38
B**	Oklahoma Natural Gas Company	4-1/2/51	8-36	
B**	Panhandle Eastern Pipe Line Co.	4/52	11-37	
B*	North Central Gas Company	5-1/2/55	3-38	
B**	Macon Gas Company	4-1/2/52	10-38	
B*	New Mexico Gas Company	5/51	1-39	
A	Arkansas-Louisiana Gas Company	4/51	1-39	

A**	Very high grade investment bonds.
A	Investment bonds believed to be reasonably safe.
B**	Obligations which possess good security, but which need constant watching.
B*	Obligations wherein the speculative element is present. Not suitable for trust funds.
	All groups but B* are suitable for bank investment.

(EXHIBIT 147 was offered and received in evidence over objections of counsel for each of the two Commissions who were granted exceptions. EXHIBIT 139 was received in evidence over the objection of counsel for each of the Commissions to whom the Examiner granted exceptions. EXHIBIT 140 was received in evidence over the objection of counsel for each of the Commissions to whom the Examiner allowed exceptions.)

1070 JOHN A. COOKE, a witness for defendants, testified:

(October 2, 1939.)

Direct Examination by Mr. Morgan.

My name is John A. Cooke. I live at Evanston, Illinois. My office address is on La Salle Street, Chicago. I am a Certified Public Accountant. I am a partner in the firm of Peat, Marwick, Mitchell & Company, and we practice under the term "Accountants and Auditors." I have been a partner in that firm since the end of 1930. I went with this firm in 1920 but was admitted to partnership in 1930.

Prior to going with this firm I received my accounting training in England and was articled with a firm in Manchester, England, for five years. I received a degree for accounting in England.

Our firm is equipped to handle all types of professional service which are considered to come within this profession. Our work includes generally: auditing examination for registration of securities with the S. E. C.; Federal income tax work; returns and investigation work; industrial accounting; and systematizing the accounting records of companies. We also go into specialized lines, including banking examinations, brokerage examinations, and other activities of that kind. We cover the whole field of accounting service. We have twenty-eight offices in the United States geographically spread throughout the country, with headquarters and executive offices in New York. I am one of three partners residing in Chicago.

You have asked me to assume for the purpose of the observations I shall make hereafter the following facts: that defendants have a maximum life of 16 years; that the proper rate base on which they are entitled to earn, if they be subjected to regulation under the Natural Gas Act, is $75,000,000; that a proper annual rate of return is 8% of that rate base; that in order to distribute the burden of returning to the investors the capital or the amount of the rate base a fund is to be set up in equal annual installments over the period of 16 years; that these companies have bonds outstanding which bear 6% interest; that during the next 16 years amounts aggregating substantially $10,000,000 will be required for the purpose of additional property as opposed to replacing property for use in the operations of defendants; that 1.35% is the rate of interest which would be received by an investor in Government bonds, the most nearly risk-free of any securities available for the investment of a trust fund; that this fund of $75,000,000 is to be returned to the investors who now own the securities of the company at the end of 16 years and that provision is to be made distributing the burden of returning that capital among all those who purchase gas during that period of 16 years by setting up equal annual installments or installments accrued as a reserve for the return of the capital. (Objection by Counsel for the two Commissions overruled.)

Based on those assumptions, this $75,000,000 can be accumulated through a sinking fund. It could be accrued, of course, by dividing the amount by 16 and setting up 1/16 of $75,000,000 every year. However, inasmuch
1071 as money held for any length of time can be put out
at some rate of return, it would be helpful to the fund to use the sinking fund means and accumulate the income which would arise from the investment of funds placed either with a trustee or held by the company itself for some future purpose.

A sinking fund, generally speaking, is a fund which is set aside outside of the control of the company for a specific purpose. The money is turned over at fixed times, maybe annually or semi-annually or over some other period, and divorced entirely from the company's control and operation, so that the money once placed in the hands of the trustee is then available to that extent to repay the sum ultimately to be accumulated in that fund.

In this particular case, having assumed $75,000,000 to be returned, a fund would have to be provided over a period of 16 years, which, by annual sums placed in it, would accrue in one of two ways, either of itself to $75,000,000, or with the addition of interest earned to $75,000,000 at the end of that period. If it accrues itself to that sum, the method would be what is commonly known as a straight line accrual. If the sinking fund method is used, the interest to be added to the annual installments must come from outside the company's activities. I make that statement for the reason that the company, as you have assumed, is entitled to a return of earnings. Then the earnings must of themselves go into the direction to which they are intended to apply, namely to the security holders. Therefore, if any rate fixed—I am now speaking of rate of income, of fixing the earnings of the company—is such that it only allows the amount which is required or permitted under the rate rulings to return a sum of money to the security holders plus an amount which is determined under the ruling for the amount to be paid into the sinking fund each year, then there is no margin over and above that to help accumulate in the sinking fund any sum beyond that which is placed in as principal rather than interest.

If the money which is placed into the sinking fund is invested outside, then the activities of others working with that money return, presuming there is no risk, an earning to the fund which does not in any way affect the company's operations, but in that case the outside money helps to build up the amount to be accumulated. The interest must come from the outside, however, if it is to be of any help in the sinking fund accumulation.

If there are bonds and stock ownership equities which represent this value of $75,000,000, this 8% per annum on the rate base amounts to $6,000,000. That amount is available as a return on the assumed value of the property and should go to the security holders, whether they be of one kind or another. It goes as far as is needed as interest, and the balance will be paid as dividends. The amount available for dividends depends upon the amount of interest that has to be paid on outstanding interest-bearing obligations. If there were no bonds, then the entire 8% would go to the stockholders as dividends. If the outstanding bonds assumed are retired as time goes on, any retirement of bonds increases the amount in dollars and cents available to the stockholders. This $6,000,000, which represents the accrual resulting from applying the rate of return to the rate base each year, is a fund that remains constant and belongs to the interest-bearing securities and to the stockholders as dividends in such amounts respectively as the amount of interest and amount remaining for dividends may happen to be at any given period during the continuance of operations.

1072 I have already said that the interest must come from without. It is immaterial what rate you use as far as the source from which that income must come.

If you could get 6% from outside investments, safe investments, so that the fund would not be impaired at the end, then I could have no objection to using 6% as the accumulation, regardless of where it came from. However, to go further, I say and maintain that it must come from without because, on the figures first assumed, the $6,000,000 belongs to the security holders as earnings year by year without any detraction therefrom.

On that assumption any saving, so-called, by the purchase of the company's own bonds merely alters the relation between interest and dividends in the 8%, and since a lesser amount must be paid for interest, a greater amount then is available for dividends to the stockholders. If you attempt to build up the sinking fund with the 6% obtained through the so-called savings on the bonds you have bought, you then and to that extent divert income permitted under the assumed 8% on $75,000,000. You divert that income to a capital use, and it is not then available for an earnings use. In other words, if the saving in interest be added to the amortization accrual, that saving is at the expense of the equity holders. You cannot spend it and have it. As you have two figures to work for and you only have a certain amount allowable, it can be used only one way or the other, and if you use it as the compound interest feature of the fund, or pay it into the fund without any recovery in the rate set, then it decreases the amount available for the stockholders as dividends.

On the assumption of the figures already given, $75,000,000 accumulated on a sinking fund requirement, computed on a 6% compound interest basis, would in approximate figures require two million nine hundred some-odd thousand dollars per year to be paid into the fund for sixteen years. That money is compounded at 6%, and we must assume further in that compounding that you can retain the 6% investment and keep on paying interest with such bonds outstanding and that you can use the interest to reinvest in bonds for the full amount of the $75,000,000. If there are not $75,000,000 worth of bonds, you cannot follow that plan by the 6% investment in the company's own bonds; but leaving that for consideration later, let us presume there are $75,000,000 worth of bonds in this case. At the end of the first year the payment would be $2,825,000 approximately. At the end of the second year you would pay into that fund $2,925,000 in cash plus the interest on the $2,925,000 worth of bonds which presumably had been acquired. That, on a 6% interest basis, is pretty close to $170,000 interest.

I do not propose to follow that through, since these figures can be checked by any method of calculus, but at the end of the tenth year, for example, to illustrate the point, we would still pay this figure of $2,925,000 into the fund, and under such an arrangement I must assume that the amount last stated has been allowed for rate purposes. I must also assume for my illustration that the 8%, the rate of return, on $75,000,000 is usable, in which case the $2,925,000, as I said before, must be placed in the reserve fund. The $6,000,000, which is 8% on $75,000,000, the total amount returnable to the security holders, is the return on the $75,000,000 and is the only fund out of which any payments can be made; but under this sinking fund of 6%, in that year you have approximately $2,000,000 that must be placed in the fund for the accumulation of interest. Therefore, the $2,000,000 can only come
1073 out of the $6,000,000 balance of earnings there,
leaving only $4,000,000 for the security holders, which amount is not 8% return on the $75,000,000. In other words, 16 times $2,925,000 lacks $28,000,000 of accumulating $15,000,000 in 16 years. Unless the interest added to make up this $28,000,000 comes from outside the company's operations, it must come out of the sum representing the 8% allowed on the $75,000,000 rate base. In the ultimate wash-out the security owners would be short just $28,000,000 of the two funds to which they are entitled as the owners of the securities of the companies.

Cross-Examination by Mr. Slaff.

Our firm does accounting work for Cities Service System and its subsidiaries. Among other companies we have represented are the successor to the Texas-Louisiana Power. We did some work for General Water Works. We did work in the Associated Gas Group recently for the receivership. We have done some special work in connection with the reorganization of Middle West. In recent years we have done work for the New England Power group, formerly in the Insull group, and I believe some of their work is still handled by our Boston office. I do not know the names of those New England companies. They are in Augusta, Maine. We have done work for the Kentucky utilities before they went into the Insull group and while with it, and for other Lexington utilities. We have done some work for the Motor Coach Group. This is all that I remember, although it is not all of the work we have done in the utility field.

I have never testified on the subject I have covered in my testimony here. I have never testified for any utility.

Redirect Examination by Mr. Morgan.

I have never testified in a proceeding involving natural gas producing and pipeline companies.

(EXHIBITS 141 and 142 were received in evidence over the objection of counsel for each of the two Commissions, to whom the Examiner allowed exceptions.)

1074 J. A. EMERY, recalled by defendants, testified:

(October 3, 1939.)

Direct Examination by Mr. Morgan.

I have testified before in this case. In my former testimony I stated that I had made a study of two phases of this case, namely, the going concern value assignable to the properties of the two companies and the rate of return which is required on the rate base. I stated in my testimony before that my firm, Ford, Bacon and Davis, Incorporated, is engaged in a general engineering business. They have engaged in practically all of the phases of the natural gas business beginning practically with the beginning of the development of natural gas. As I stated before, they have made original estimates, surveyed marketing prospects, designed and constructed lines, participated in the financing or the raising of necessary capital, developed the markets, operated the lines, and actually marketed the gas in the course of their activities. We have had an interest in the Southern Natural Gas Company, which purchases its gas in the Louisiana fields and transports it to Alabama and Georgia.

In connection with my preparation in this case and in other cases, I have given thought and study to the subject of financing a natural gas pipeline project and to the necessary rate of return to attract capital to this character of business. To obtain the money necessary for the establishment of the enterprise, it is necessary to hold out sufficient inducement. First the safety and facility of conversion of the capital must be provided for, and second an adequate rate of return. By safety of investment I mean that a man who is investing capital desires to make sure that he will get it back. I am referring to the return of the capital through provisions for returning the capital intact at some time in the future or the facility for selling out the properties.

Most all enterprises entail risks, some more than others, so the degree of risk must be carefully examined into. An investor is interested in the degree of risk involved in connection with the return because that is an index of the safety of his principal and his interest on the return of the capital. It makes a difference to him as to the risk involved. The greater the risk, the greater the return he must have.

By rate of return I mean the annual compensation for the use of the capital. That means the amount remaining after all charges to which the company is subjected, including operating expenses, taxes, and, in the case of an extractive industry, depletion or amortization.

I spoke about the influence of risk or hazard and have stated that the greater the risk, the greater the return must be in order to induce capital to enter a particular kind of enterprise. As I have already stated in my former testimony, I am familiar with the natural gas business and that my firm has had to do with a great many different types of enterprises and activities. The natural gas industry, particularly when it includes production, is more risky than the average business. When compared with an ordi-
1075 dary utility such as an electric utility, a manufac-
tured gas utility, a water distribution company, or any type of continuing enterprise, there is more risk involved in the natural gas business. I say this primarily because it is a so-called extractive or mining industry, but there are other important reasons. The pipelines are subject to most of the risks of the distributing companies who purchase gas at wholesale from the pipelines. In addition to those risks, the pipelines have risks peculiar to themselves. The reason I say that the pipelines have the same risks as the distributing companies is because if the busi-

ness of the distributing companies suffers, the business of the wholesaling pipeline from whom these distributing companies purchase their gas must suffer also. The amount of gas available on which the life of the pipeline depends is bound to be known only to the extent of an estimate, the geologist's estimate, which may or may not be right. The field also is subject to drafts for other purposes, such as other pipelines, carbon black manufacture or gasoline processing. Then the field as it stands is subject or may be subject to damage in the future by the intrusion of salt water or the migration of sour gas into sweet gas areas.

It is not possible to predict with certainty the full extent of the drafts on a field over a long term of years. There is always a possibility that others will enter the competition for the product itself. If another pipeline should be built from the same source of supply, or if other carbon black industries should enter the field and utilize sour gas for the manufacture of carbon black, such a development would tend to limit or reduce the amount of gas available for these companies, and it would shorten the life of the companies and would increase their operating expenses in later years by reason of the reduction in pressure.

If we assume that through the investigations and researches of the geologists the extent of the present reserves of gas in the Texas Panhandle field can be ascertained with a reasonable degree of certainty; that the number of wells that have been drilled and which will hereafter have to be drilled can be ascertained with a reasonable degree of certainty; and that the cost of operating those wells and maintaining the equipment used in connection with the production of gas from these wells, and the operation and maintenance of the other pipeline equipment, including the pipeline itself, the compressor stations, and other facilities, can be ascertained with a reasonable degree of certainty under conditions assumed to be most favorable; the providing of an annual reserve for amortization over the indicated life of the field based on such assumptions does not remove the hazard involved in the question of whether or not the capital of these investors will be returned to them by the time the field is exhausted. It is almost certain that in a term of years there will be some circumstances not favorable, even assuming that the market is always available and favorable, or the estimates are made altogether under favorable circumstances. If the funds provided for the return of the capital be distributed over the entire indicated life of the field, which, in the light of defendants' testimony, we will assume to be 16 years from the first of January, 1939, an investor would consider his money subject to hazard because he could not count definitely on all conditions being favorable. That circumstance makes the required rate of return to attract capital higher.

1076 The fact that estimates of the kind I mentioned a little while ago are always attended with uncertainty and that the field might last a year or two longer than 16 years instead of playing out or becoming exhausted one or two years short of that period does not remove the hazard I mentioned. Of course, it reduces the odds somewhat but does not remove the hazard. It is naturally always a guess in the natural gas business as to whether a field may run longer or shorter than expected. If it should run shorter than expected, the investor has very litle chance of recovering all his capital. If it runs longer than expected, the situation must be dealt with according to the conditions at that time by the regulating body. The Federal Power Commission cannot protect the investors in defendant's properties against losing a part of their capital due to the lives being shorter than that indicated by the testimony under the most favorable conditions principally because his business is a highly competitive one, and even if they were permitted to charge higher rates in an effort to recoup the deficit, they could not get them. Secondly, the process of getting rates raised is something that requires time. In the first place, the condition has to run long enough to constitute proof, and in the second place, it takes considerable time to establish that as proof.

Since this company operates in several states and is itself subject to Federal regulation, it would have to expect more than one rate proceeding before it could succeed in increasing its rate. There would be a rate case in the Federal Power Commission, and every one of the distributors purchasing gas from this company would have to go and get its rate increased in order to meet the increased price which the Federal Power Commission might provide.

There is a hazard involved in the circumstance that the pressures of the gas any place in the field will inevitably decline as the gas is withdrawn from the reservoir from which it is taken. As the pressure declines the yield of gas declines, and the cost of pumping it from the wells and putting it into the lines increases. The circumstance that the volume of recoverable gas from a well decreases as the pressures decline is met by the drilling of more wells so far as the field will permit. In other words, it requires more wells to produce 210,000,000 cubic feet of gas at 175 pounds pressure than it would at 350 pounds pressure. The record shows, as I am informed, that the company has undertaken to predict the cost of additional wells which they can now foresee, the cost of providing field compression necessary to get the gas from the wells into the main line, and the minimum cost incident to the drilling of such wells and the boosting of the gas into the line.

If it be assumed that these predictions are accurate, they do not remove the hazard, because it cannot be expected that all conditions will be favorable for 16 years. Even if the witnesses have testified that to the minimum figures for capital replacements and for maintenance should be added 10% to cover hidden requirements or contingencies that cannot now be definitely foreseen, the hazard I have been discussing is not removed, because that allowance for contingencies does not apply to the operating expenses. While an investor would doubtless require protection to the extent of 10% for contingencies, he would still feel that there were hazards beyond that.

1077 There are other hazards confronting the investors in these particular pipelines. There is naturally a considerable hazard attached to a line 1,000 miles long. In this particular case the line is operated at high pressure and is so designed that there is a higher stress on the metal than on any other line that I know of. The stress utilized by these pipelines is approximately 70% of the elastic limit and something less than 50% of the ultimate strength. That is considerably higher than the usual stress at which steel is worked in the transportation of natural gas and entails great vigilance and skill on the part of the operating organization. This is true because of possible variations in the texture and thickness of the metal, because of the possibility of mechanical shocks, and because of deterioration due to the impact of changing pressures. When stress is applied and taken off and then applied again a great many times it produces some deterioration in the metal and in its strength. That is a subject about which a great deal is not known at the present time. It is commonly referred to as fatigue.

There is no history prior to the operations of these pipelines from which they can arrive at a certain conclusion as to how long they will be able to continue applying the stresses at which they are now working the steel. This is the only pipeline system that I know of which applies such large stress. The fact that for the past seven years, or nearly eight years now, this pipeline has been in operation and that during the last three or four years it has subjected its equipment to this stress and that notwithstanding some breaks and interruptions they are still operating the lines at such stress and are transporting 200,000,000 to 210,000,000 cubic feet daily through the lines, does not mean that they will continue to be able to do that indefinitely over a period of the next 16 years. Deterioration of the metal must be looked for. I should have added that in the welding and construction of the line there are internal stresses set up in the metal, and when those operate together with the stresses due to the load they might exceed the elastic limit. Such cases are likely to turn up not only at the beginning but at any time during the life of the line.

If as a result of these high stresses and the aging of the line it should turn out that the volume of gas and the pressures at which that gas is transported are too large or too high, the immediate result would be the expense of repairs and the interruption of the business, but if it became necessary to reduce the pressure, it would reduce the earnings substantially. The situation could be handled only by reducing the pressures at which the gas is transported. Naturally, that would result in a smaller volume of gas moving through the system.

As the senior vice president of my firm and a member of its executive committee I keep in touch with all of its activities. Naturally I keep closer in touch with some things than with others. Of course, I cannot keep in touch with all of them as to details. The firm entered the natural gas business in about 1907 when they made a very extensive study of the natural gas business in West Virginia and western Pennsylvania as a part of a report on the Philadelphia company which owned these properties. As a result of this report the syndicate invested in the Philadelphia company, and the firm took an interest in that syndicate. The Examiner asks me ~~how I fitted~~ into that study. My answer is practically not at all. I was in the south at that time, and came to the New York office later than that.

1078 The first intimate contact I had with the natural gas business was in a study of the market of the Union Gas Company, operating largely in southern Ohio. Then I organized and for about six months was in charge of a valuation of the East Ohio Gas Company, the Peoples Gas Company, and the Hope Natural Gas Company. After my intimate connection with that valuation I was engaged in consultation from time to time as long as the work was in the office.

Questions by the Examiner.

All phases of the business were covered in that connection because it was supposed to lead up to a rate case. I do not remember definitely what was done regarding rate of return in which the matter of hazard would have been discussed. For the past twenty years I have been more or less intimately connected with natural gas matters. That has been one of the activities of the office. Financing matters are almost always discussed among us. I do not know of any of them that have been under my supervision in that respect.

I had some rather intimate connection with the projection and construction of the Edmonton system in Alberta, Canada. The matter of hazard in the natural gas business is something that is always thought of in connection with natural gas operations. In connection with my preparation for this testimony I consulted with engineers very thoroughly as to the operating characteristics of these pipelines. In our office there are several engineers who devote practically all their time to this business, and I discussed it very thoroughly with them. They advised me as to what the hazards would be in the operation.

Direct Examination by Mr. Morgan Resumed.

I sent one of my partners, Mr. Hill, who devotes practically all of his time to the natural gas business, over the properties of these companies and have a report from him directed to me concerning the stresses under which the lines are operated and the operating conditions which he found there. Mr. Hill is an engineer. He was vice president and had entire charge of construction and the first two years of operation of the Edmonton Company. He had charge of construction of the Interstate Company and was its president for several years. He had charge of construction and was general manager for several years of the Colorado Interstate. He had charge of construction and was vice president of the Southern Natural Gas Company for several years.

I think the public would consider these hazards in their attitude toward investments in natural gas properties. My firm has participated in the sale and in the financing of such a company. My firm built 250 miles of the line involved here. Mr. Hill, the man who went over the property, as I stated a little while ago, was the man in charge of that building. The line crosses about thirty rivers, most of which have changeable banks, so that in a great many cases there is danger of the disruption of the line by floods. It is a very important hazard because it entails a good deal of money for repair and loss of business during repair.

There is also danger from landslides and earth settlement and mechanical shocks due to obstructions in the line.

At the distribution end of the line this company's 1079 business is subject to the same hazard as the distributing company, in that it is in competition at all points with other fuels. The principal market for domestic gas is in cooking, and that is being encroached on by electric cooking. House heating by gas is in competition with oil and coal. All industrial gas business is highly competitive. The company is continually faced with a restriction in business due to changes in the prices of coal or in the methods of burning it.

These companies are subject also to the general hazard of inflation. A large part of the governmental agencies are operating under unbalanced budgets. That means that sooner or later they will have to be worked out either by increased taxation or an inflation of the currency. An inflation of the currency would mean that wages and all prices of materials would have to be increased. The other alternative of increased taxes would affect these companies. It has affected them already. More taxes have been applied than were in force at the beginning of operations, and the rate of taxation has been raised. My staff and I have investigated the books and records of the company bearing on its operating costs and its taxes and other costs of that character. We have found a substantial increase in the taxes, both in number and in rate per thousand. These increases might be met by increased rates after a rather expensive delay, but first they must conduct operations at the increased cost long enough to give proof.

It is my view that investors in natural gas securities have taken cognizance of the risks which I have discussed here, and would take cognizance of the special hazards confronting these companies, and that they have considered these risks in the prices they have paid for natural gas securities. I am able to determine that they have taken cognizance of these hazards by comparing the ratios of market price to earnings. I have made a study to determine what appraisal the public has made of these risks and hazards. First I made a search of market and financial records and have obtained a list of all natural gas companies having transmission lines, all of the securities of which are dealt with so that market prices can be obtained, and I have found 11 companies which answer to that description. I confined this study to those which have transmission lines so as to get companies as nearly similar to this one as I can. I make a distinction between a company which owns distributing facilities only and those which own facilities for producing and transporting gas. The risk is less in the case of companies which distribute only, and I have not included them for that reason. The risks in the case of companies which distribute only are less because their property will be useful after the natural gas reserves are exhausted. All of the capital does not become useless upon the exhaustion of the source of supply, and the distributing companies are less subject to competition than pipelines.

The fact that a transmission line owns a distributing company and is not one standing on its own bottom, that is, one which is confined to transmission and/or producing properties, is a circumstance which enters into the risks involved in the securities or capital investments. The ownership of a distribution system which buys from the pipeline insures to the pipeline the control of the market and also adds to its total investment a proportion of lower risk property. All of its investment is not tied up in something that will be lost when the source of supply has been exhausted.

1080 I have not included in this list of 11 companies all the pipelines which are engaged in the transportation or production, or the transportation and production of natural gas, but only those for which I could obtain records of the market sales of all the securities. I have no way of knowing how the public appraises the securities except by what the public has done when the securities were offered for sale and when they have been sold in the exchanges and markets. I consider that the best evidence of value and of the required ratio of investment to return.

(At this point counsel handed the reporter a document entitled "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Data Concerning Rate of

Return, Witness J. A. Emery," with the request that it be marked for identification. At the direction of the Examiner the document was marked Exhibit 148 for identification.)

The list of companies who own transmission lines, concerning which I was able to get the data above mentioned as to the fair appraisal of their securities, is: Interstate Natural Gas Company; El Paso National Gas Company; Memphis Natural Gas Company; Southern Natural Gas Company; Lone Star Gas Corporation; Mountain Fuel Supply Company; National Fuel Gas Company and its subsidiary Pennsylvania Gas Company; Union Gas Company of Canada; Kansas Pipeline and Gas Company; and Oklahoma Natural Gas Company.

Of these 11 companies only one is confined to the production and transmission of natural gas, the Interstate Natural Gas Company. Three are confined in their operations to the transmission of natural gas. These are the El Paso Natural, the Memphis Natural and the Southern Natural. The next five are what we call integrated operations. They include in their operations all three activities, production, transmission, and distribution. The other two, the Kansas Pipeline and the Oklahoma Natural, have transmission and distribution but no production, except that the Oklahoma Natural has a small amount of production.

I have listed these companies on page 1 of Exhibit 148. The group of figures in the first three columns of this exhibit gives the market appraisal of the value of the securities at the high price of the year 1938, at the low price, and at the average price between the high and the low. The next column shows the earnings in 1938 applicable to return on investment. The next group of three columns shows the rate which the earnings bear to the market appraisal at the high prices, at the low prices, and at the average, respectively.

The figure $23,823,825 shown under the subcaption "High" in the first column of figures opposite the name Interstate Natural Gas Company on page 1 of this exhibit is arrived at by multiplying all of the securities outstanding by the high price of the year. (Objection by counsel for Illinois Commerce Commission overruled.) There were 952,953 shares of common stock of no par value outstanding, and the high price of the year was $25 per share. Multiplying the number of shares by the price gives us a total of $23,823,825. There is nothing but common stock outstanding in that company. The low price paid for that company's stock during the year 1938 was $17.50 per share and the high price, in 1938 was $25.00 per share.

1081. If you figure the value of all the stock at the high price, you get the valuation already stated, which, applied to the earnings of the company applicable to this stock, gives an earnings price ratio of 8.53%.

Over there under the caption "Annual interest and earnings" as set out the earnings for the year 1938 applicable to this stock. These earnings are after all necessary charges, such as operating expenses, taxes, depreciation, amortization, etc. This return is attributable to the stock itself and is available for dividends on the stock.

If we multiply the total number of shares by the lowest price paid for these shares during the year, we find the market value is $16,676,678, which, applied to the earnings, gives an earnings price ratio of 12.19%. Those are the figures shown in that line on page 1 for the high and the low. The average investment and the average return are obtained by taking the average of the investment valuation and dividing it into the earnings, which produces 10.04%. The reason I have taken the high and the low and the average is that it is hardly fair to take a figure for the valuation of one of these properties based on the sales in one day, and I consider the fairest way is to take the sales over the range of the year and show the highest and the lowest. The result we reach is what I have termed the public's appraisal of the value of that stock at the high price, the low price, and at the average.

These rates of return shown in the last three columns here are the actual yields in 1938 based on the high price and the low price and the average of the two prices which the investors in that stock actually earned in 1938.

I got the information as to the other companies in exactly the same way. In the case of the other companies there was generally a variety of securities, bonds and stocks. On page 3 we find the detail as to the securities of the El Paso Natural Gas Company. On the first line there were $6,000,000 face value of 3½% coupon rate bonds outstanding. There was no market quotation during 1938 on those bonds, but there is a record of a private sale at 98½, and I have consequently used that price for both the high and the low. There were $3,480,000 of Serial Bank Loans. Those are not traded in, and I have entered them at par. The bank never advances any more than the principal of the note. There were 14,797 shares of 7% preferred stock which sold at a high of 109, giving a valuation of $1,612,873, and at a low of 102, giving a valuation of $1,509,294. There were 600,853 shares of common stock, of which the high price was 29⅞, giving a valuation of $17,950,483, and the low price was 17, giving a valuation of $10,214,501. The total valuation of these securities at the year's high price was $28,953,356 and at the low price was $21,113,795.

The next column shows the interest applicable to the bonds and loans, the 7% applicable to the preferred stock, and the balance applicable to the common stock, making a total of $2,479,154. This was 8.56% of the valuation at the year's high price and 11.74% of the valuation at the year's low price, and those figures haveen carried into the line opposite El Paso Natural Gas Company on page
1082 1, to which I have added on page 1 the average of the
market price and the average return. The average return on the average of the high and the low appraisals was 9.9%.

(Mr. Timberlake, assistant to the witness, made the following statements which were adopted by the witness: "I do not have the face amount of the first mortgage bonds under sale at 98½ that I was discussing. It will require quite a little investigation to determine how many shares or bonds were sold at that particular price, and unless it was listed on the open Stock Exchange, it would be impossible to get the number of shares or bonds that were sold at the price. The first mortgage bonds were all sold at that price. It was not a public offering. It was taken by private interests and the whole issue was $6,000,000)."

I have the same detail as to each of the other nine companies worked out on pages 4, 5, 6, 7, 8, 9, 10, 11, and 12 of the same exhibit. I dealt with just the securities that were outstanding and which were negotiated during that year, and if I did not have such securities, I did not use the companies'. It was only those securities on which the public, either by public sales, or by private sales, made an appraisal value of the securities by the price it put on those securities. Turning back now to page 1, we find that based on the highest market valuations the one company classified as a production and transmission company earned 8.53% on the highest appraisal of its securities, 12.19% on the lowest appraisal, and 10.04% on the average of the high and the low appraisals. I would say that this company, the Interstate Natural Gas Company, comes nearer to the Natural Gas Pipeline Company of America than any other company on the list in that it owns only production and transmission facilities.

The investor in the securities of the three companies following this one, which I have classified as transmission companies, earned at the high price 8.03%, at the low price 10.4%, and average of 9.06%. I should have said regarding the Southern Natural Gas Company that besides a small amount of production it also has a small amount of distribution. It owns two small distributing subsidiaries.

The next five companies, which I have described as integrated companies, omitting the Pennsylvania Gas Company, which is a subsidiary of the National Fuel Gas Company, earned 6.62% at the high price of the year, 8.8% at the low price, or 7.55% at the average between the high and the low price.

he other two companies, which I have classified as transmission and distributing companies, earned at the high price of the year 6.18%, at the low price 8.06%, an average of 7%. The over-all average of all these companies, including all four of the classes of companies, earned at the high price of the year 7%, at the low price of the year 9.28%, an average of 7.98%.

It seems to me very clear that the companies shown in the upper brackets, that is beginning with the production and transmission, require higher rates of return than those in the lower brackets, which are confined to transmission and distribution. As between those engaged in production and transmission and those which have no production, there is a distinction evidenced by the fact that the average return required in the one instance is 10.04% and in the other an average of 9.06%. When we introduce the distribution facilities the required return is still further reduced, and is there only 7.55%. When we eliminate the production from the integrated company, the required average is 7%, which is still lower than that of the integrated company which owns production. As compared with the average of all of them, these figures indicate that the investor requires from 1% to 2% more for those companies which have no distribution facilities.

Page A of Exhibit 148 contains a summary of the average required rates of return to which I have just testified.

It shows the same information in summary that is shown in the last three columns on page 1, grouping the companies as we have grouped them on page 1.

On page 4 where we have "B—Taken as Par," the reference is to bank loans which we considered to have the value of par. I don't think the footnote C on page 5 enters into the computation in any way except to show a division of earnings between the Class A and Class B
1083 stock. On page 9 the footnote B points out that there were apparently no sales, and the price was based on the end of the month bid quotations. I pointed out that the data for this company was not used, however, because it is a subsidiary of the National. It is set forth on page 1, but the figures concerning its earnings did not enter into the average. To the footnote B on page 10 I might add that I think the earnings applicable to these issues mentioned in the footnote B are not included in the annual interest and earnings applicable to the securities listed. In footnote D on page 11 it is noted that the information was obtained from a Securities and Exchange Commission report. I think it was in connection with some financing. It is a study that the S. E. C. makes every year of public financing of public utility securities.

Cross-Examination by Mr. Booth.

I have a general knowledge of some of the companies included in Exhibit 148. I studied the public reports of various companies, and I conferred with Mr. Hill, who is quite familiar with most of them. I mean the same Mr. Hill, an officer of my firm, to whom I referred in my testimony earlier today. He has devoted practically all his time to natural gas matters for 18 years since he has been with us, and for several years prior thereto. As to whether or not I am in a position to state how these companies and their operations are comparable in a specific way to the operations of defendants, that depends on how far you want to go specifically. The Interstate Natural Gas Company produces and transmits gas and buys some gas. It sells its gas largely, if not altogether, under contracts calling for large deliveries. Its transmission line is considerably shorter than that of Natural Gas Pipeline Company. It is only about one-fourth as long. As to whether this line is comparable to defendants' line, it is not as large as the Natural Gas Pipeline Company of America.

Questions by the Examiner.

The pipeline is about 250 miles long, as compared with 950 for defendants. In size the pipeline is 22 inches in diameter, and it extends from Monroe field in northeastern Louisiana to a point below Baton Rouge. It has the same physical obstacles to overcome that the Natural Gas Pipeline Company has. Its principal markets are Baton Rouge, and at a point to the south of Baton Rouge it connects with the pipeline to New Orleans, which it supplies. It sells at wholesale to a transmitting company that in turn supplies New Orleans. I don't know just what the connections are between that transmission company and the distribution company in New Orleans. I think they are both owned by the same parent company.

The capacity of the pipeline is 160,000,000 cubic feet per day. I don't know just what the division of business is, but I think that roughly half of it is sold at Baton Rouge and half of it goes south. In Baton Rouge they supply the local distribution company, but principally the refinery of the Standard Oil Company. If the Standard Oil Company's refinery in Baton Rouge were to be left out, I don't think the industrial load in Baton Rouge is comparable to that in Chicago. They supply the company which supplies the domestic market in Baton Rouge. The demand for domestic gas in Baton Rouge I would say is somewhat less than in Chicago per capita because of the less heating required and the large Negro population. The population of Baton Rouge is about 50,000. That is not comparable to Chicago in size.

1084 *Redirect Examination by Mr. Morgan.*

Due to the fact that these companies have a pipeline which is about four times as long as that of Interstate Natural, the defendants have the greater hazard. There is more hazard in a 1,000-mile line than there is in a 250-mile line. I stated a little while ago that the line is 22 inches. They have some 22-inch line. The line from Baton Rouge to New Orleans, which is owned by the Southern Gas and Fuel Company, a subsidiary of United Gas Company, is an 18-inch line.

(EXHIBIT 148 was offered and received in evidence over the objection of counsel for each of the Commissions, to whom the Examiner allowed exceptions. EXHIBITS 144, 145, AND 146, offered in evidence at a prior date, were admitted in evidence without objection.)

From the notes I have with me I am not able to prepare a complete answer to the Examiner's questions as to what the explanation may be of the circumstance that the Southern Natural Gas Company's securities sold in the year 1938 indicated a lower return on the market appraisals of the valuations involved than did those of Lone Star Gas Corporation and the Union Gas Company of Canada. I will be prepared to discuss that point on cross-examination.

Just before adjourning Mr. Slaff asked me if the City of Baton Rouge was comparable to the City of Chicago. I had pointed out that half of the Interstate Natural Gas Company's production goes to New Orleans. I don't know just what the proportions are for domestic or city distribution. So far as the volumes are concerned, the City of New Orleans as an outlet for natural gas is comparable to Chicago.

The essential problems of production and transmission in the case of these companies listed in Exhibit 148 and those of defendants are all of the same nature, and the differences are only those of degree. I know of no case in which the problems of the Natural Gas Pipeline Company do not involve more hazard on account of differences in degree than these others set out in Exhibit 148. When I use the expression "Natural Gas Pipeline Company of America" I mean to include Texoma, for I am treating them as one project.

Another reason why these companies in my opinion would require a higher rate of return than the average of the companies with which we deal in Exhibit 148 is that there is a market for the securities or for most of the securities of the companies listed in that Exhibit. If there is no market for securities, any investment in them becomes frozen, and an investor is more hesitant to freeze his money than to invest it in something that is traded in. There is no market for the securities of defendants, and consequently, an investor would be more hesitant to invest in them, other things being equal, than in these other securities, and therefore he would require the inducement of a higher rate of return.

I point out also that this table in Exhibit 148 is prepared on the basis of 1938 prices and markets. It is notorious that on account of the plethora of money, yields were low at that time, and therefore I would think that normal yields could be expected to be higher than those shown here.

1085 Also, the projectors, investors in, and operators of these defendant companies have shown and developed an outstanding degree of skill and enterprise in three particulars. First, the pressure at which the line is operated is much higher than that on any other line in existence before it was built, and I know of no other line of any importance that is operated at anything like so high a pressure today. Second, the design and operations of the line is such that the working stresses on the walls of the pipe are much higher than on any other line that I know of. This results in a smaller investment per unit of capacity. Third, the capacity factor of this line is much higher than that of any other large system. In all these particulars these companies have shown an extraordinary spirit of enterprise, and in my opinion they should be compensated for that in the rate of return. If there is to be no incentive for such enterprise, naturally such enterprise will stop.

I have made a study of the records of this company with a view of determining the difference in the net earnings of the company available for interest and dividends that would have resulted had they followed along the established engineering practices and built a pipeline capable of operating at the then prevailing pressures. I have compared the net earnings of the company at the higher pressure under which they operate with the estimated net earnings they would have realized if they had dropped the pressure back to nearer the standard rate. (Objections by counsel to the two Commissions overruled.) I have not gone back to what other companies use but only to 500 pounds. That is, I have compared the earnings operating at about 700 pounds, as at present, with the earnings if they went back to 500 pounds. By the standard rate of pressure I mean the maximum amount of pressure used by the other pipelines, which runs from 400 to 450 pounds. Comparing the actual earnings with the estimated earnings at 500 pounds pressure, the earnings at 700 pounds pressure show 1.6% greater on the estimated cost of reproduction and 1.8% approximately greater on the book value. My comparison was based on the operating results of the years 1936, 1937, and 1938.

The actual sales for the three years averaged approximately 74,000,000 M. C. F. per annum. If the pressure were reduced to 500 pounds, it would only be possible to pass about 56,000,000 M. C. F. through the line, and that added to the field sales makes a total of approximately 59,000,000 M. C. F., as compared with the 74,000,000 M. C. F. average.

The revenue from the 74,000,000 M. C. F., including gasoline revenue, was $14,853,600. I have considered that if the capacity of the line and the amount of gas delivered is reduced, it will all come out of the cheaper gas, so that the estimated operating revenue is not decreased in proportion to the decrease in gas transported, and amounts to $13,032,914. The operating expense, variable with the volume of gas sold, now amounts to $1,741,839, and I estimate that that item would amount for the smaller quantity to $1,367,343. The operating expenses not variable with the amount sold were $2,134,630, and I have estimated that that would be the same for the smaller volume, making a total operating expense of $3,876,469 at the present time and an estimated total operating expense for the smaller volume of $3,501,974. These operating expenses also include all taxes except income taxes. Income taxes actually paid amounted to $658,839. It is estimated that on the smaller volume the income taxes would be $419,717 annually.
1086 Deducting the income taxes and the expenses from the revenue gives a net income before return and amortization at the present time of $10,318,291, and I estimate that for the smaller volume the figure would be $9,111,223, or a difference of $1,207,067, which is 1.8% of the book cost and 1.64% of the estimated cost of reproduction new less depreciation. I used the figures of Mr. Hamilton as the basis for the reproduction cost new comparison. The cost of a pipeline equipped to handle gas at 500 pounds pressure would have been less than the present pipeline.

I have presented this estimate on a conservative basis. That is, if I had taken into account those lower capital costs, there would have been shown a greater saving or a greater net earning, due to the increased pressure. I have prepared these figures on the most conservative basis merely for the purpose of showing that there was at least this much of the revenue that was attributable to the employment of higher pressures. If I had undertaken to go through the laborious task of trying to develop how much less, if any, a pipeline of 24-inch capacity would cost with the old thick walled steel that was employed at that time and which would have permitted of pressures not in excess of 500 pounds, there would have been a greater difference reflected than the differences I have stated. That brings in the question of stress, on which I have not made an estimate but have testified that it results in lower operating costs.

There was this reason why I did not make the adjustment in this figure for saving in weight of pipe. I am not sure that we could get a pipe with thinner walls. If we started out to run at 500 pounds pressure, I am not sure that we could get the pipe with the corresponding lesser thickness.

Questions by the Examiner.

There are so many expenses in connection with the pipeline that do not vary with the thickness of the pipe that I do not think there is any chance that the cost of the line for operation at 500 pounds would be sufficiently less than the cost of the existing line to offset that difference in net income of $1,400,000. Prior to the investigations and the pioneering in design initiated by the founders of these pipelines there was nothing that I know of in 24-inch pipe except a thick-walled pipe. Those who are employing a thin-walled pipe and who are using 400 and 450 pounds pressure now are using the same thicknesses as were used in this line. The pipe is sold by the ton generally. I do not think there would have been much if any difference in the cost of the pipe itself between the 500 pound line and the existing line. There might have been some difference in the joints, valves, and compression apparatus. I am not prepared to say that there would be any less cost in building the pipeline out of the type of pipe available when this project was first conceived and when these men first went to work on it. I would like to state that a determination of that question would be a rather extensive computation, and I did not attempt to go into it. I therefore took what I thought was the conservative side in setting up these figures. Now I do not by any means add these figures to any previous figures that I have set up for what I think is the required rate of return. If I may anticipate my testimony, it would have been to the effect that I think consideration should be given to this and the company should be allowed a part of it in rate of return, not the whole figure. What I have really done here is to assume the same type of
1087 pipe and the same line using the lower pressure.

(Objections by counsel to the two Commissions to the above testimony overruled.)

Direct Examination by Mr. Morgan Resumed.

The rate of return which I am going to name when we get to it does not include any allowance for this additional earning on account of the employment of higher pressures. My opinion was that this improvement should be shared by the company and the consumers and that some part of this should accrue to the benefit of the company. That is something that should be allowed in addition to the rate of return to which I am about to testify. There would have been no less cost in building a pipeline of the old type of pipe unless there would have been some difference in the cost of the joints and valves. I do not know what that would have worked out to. The right-of-way would have cost no less. There would not be so much compression apparatus required for a 500-pound line. I have simply assumed this pipeline as built and equipped operating on a pressure of 500 pounds instead of a pressure of 710 pounds. I am not prepared with the figures to show how much less would be involved in the pipeline as it exists. (A motion to strike witness' testimony denied.)

Based on the investigations I have made as to the type of business in which defendants are engaged, the risks and hazards which go with that business, and the risks and hazards peculiar to their business, and in the light of the public's appraisal of that type of business and the return required, and the other facts and circumstances concerning which I have testified, I have an opinion as to the required rate of return for the defendant companies.

(Document entitled "Estimated Earnings on Account of Increased Capacity and Delivery of Natural Gas When Operating at Higher Pipe Stresses," marked Exhibit No. 149 for identification. EXHIBIT NO. 149 offered and received in evidence over the objection of counsel for each of the two Commissions, to whom the Examiner allowed exceptions.)

In my opinion the required rate of return for these two companies is between 9 and 10 per cent per year. In arriving at the figure I have named, I have given some consideration to the compensation to which defendants are entitled by reason of the skill and management of the property. If you exclude that part of the compensation and confine it to the compensation for risk in addition to pure interest, exclusive of reward for incentive or pioneering and enterprise, I would say that a fair and reasonable return or what would be a required return would be not less than 8%. I mean that such a return would be required in order to attract the capital necessary to finance these companies.

1088 WILLIAM C. GILMAN, a witness for the defendants, testified:

Direct Examination by Mr. Morgan.

(October 3, 1939)

My name is William C. Gilman. I live in Westport, Connecticut. My place of business is at 55 Liberty Street, New York. I am a partner in the firm of Gilman and Hickey. We are financial consultants primarily in the public utility field.

We are employed by corporations to assist and advise them in the development of plans in connection with the sale to the public of securities and in connection with development of financing, reorganization and recapitalization plans. We are employed by investors to investigate special situations in which they propose to invest their money. We are employed by underwriters to investigate situations where they propose to buy securities and in turn distribute them to the public. We have appraised securities for public appraisal bodies and have performed various other services generally coming within the scope of consultants in financial work.

I attended McGill University of Montreal, Canada from 1912 to 1914. From 1914 to 1919 I was with the British Army in France, as a captain in the Royal Field Artillery. From 1919 to 1923 I attended the Massachusetts Institute of Technology in Cambridge, Massachusetts, graduating in 1922 with a degree of Bachelor of Science, and in 1923 with a degree of Master of Science.

I am a licensed professional engineer in the State of New York. Since my graduation from the University, I have been employed by the General Electric Company, the Central Hudson Gas and Electric Corporation, the Electric Bond & Share, and the Carolina Power and Light Company. While I was with the General Electric Company I was in the Engineering Sales Department from 1923 until 1925. From 1925 to 1927, I was with the Central Hudson

Gas and Electric Corporation as manager of a division of the Commercial Department. In 1928 I was with the Electric Bond & Share and the Carolina Power and Light Company primarily in training to go abroad. From 1928 to 1935 I was with the Equitable Life Assurance Society of the United States as engineer in the Treasurer's office.

In the last-named position, it was my responsibility to investigate, make trips over and study public utility and industrial companies, to prepare reports thereon and recommendations for the Treasurer and the Finance Committee with reference to possible investments by the Society in the securities of the particular companies. The Equitable is one of the large insurance companies, one of the five largest in the United States and, as such, invested many millions of dollars each year. In the field in which I was responsible the comparative figures representing investments in securities were $100,000,000 in 1928 and $300,000,000 when I left them in 1935.

It was my duty to visit the public utility and other companies, to inspect their properties in the field, in-
1089 vestigate every phase of their business, to prepare appraisals of such companies for our own purpose, to prepare comprehensive reports of such companies, and make recommendations to the Treasurer and the Finance Committee with reference to the investment policy with respect to that particular company. My duties required me to take note of the risks and hazards that confronted the company I was investigating. The type of securities usually acquired by the Equitable were bonds. The fundamental policy of the Society, which is an insurance company holding trust funds, was to obtain safety in investments, and it was all the time looking for safe places to put money. It was, of course, at the same time trying to obtain as satisfactory a yield as possible, commensurate with the safety which we demanded. There is very definitely a difference between the factor of safety of an investment in bonds and one in preferred stock, the given conditions being the same. The bond is usually secured by a mortgage upon the property and the issuing company covenants that if conditions are not met, the property goes over to the bondholders. It is a definite promise to pay. The preferred stock is simply a share in the ownership and a promise to pay dividends ahead of anything being paid on the common stock. The preferred stock is senior to common stock and consequently much safer from an investment

point of view. The risks involved in bonds are not necessarily commensurate with the risks that are involved in the total investment or in the investment looked at as a whole. The securities represented by bonds have the first call on the total earnings of the enterprise and are safer than an investment in the whole enterprise.

In the early days of my employment with the Equitable, we had no holdings at all in the natural gas pipeline industry. During the latter part of my time with the Equitable, we did start looking into the industry and we did make certain investments in the industry. I remember the first one that was made by that Society. It was an investment of approximately $4,000,000 in the bonds of the Northern Natural Gas Company. That was the first large purchase by institutional buyers of the bonds of a natural gas pipeline company. They bore a coupon of 4¾ percent, originally 5 percent by contract but reduced to 4¾, and they were a very short maturity—12 years. The Metropolitan Life Insurance Company, the Prudential Life Insurance Company and the Mutual Life Insurance Company of New York participated in that purchase. Approximately 40 percent of the total fixed capital of the Northern Natural was represented by that issue of bonds.

I heard Mr. Delafield testify that a short time before this the Metropolitan Life and the Mutual Life bought two relatively small blocks of bonds of two subsidiaries of the Columbia Gas and Electric Company, that those companies required the Columbia Gas and Electric Company to guarantee those bonds as a condition of that purchase. From talking to the Assistant Treasurer of the Metropolitan, Mr. Mellon, who negotiated the purchase of those bonds, I learned that they would only buy the bonds of the two particular companies if guaranteed by the Columbia Gas, as they wanted that additional financial protection which they thought came with the guarantee of Columbia. (Objection by Commission Counsel overruled.) The Columbia Gas and Electric Company represented a large integrated natural gas situation and also had some electric subsidiaries of some substantial importance. The Northern Natural Gas Company is in the business of transmitting and producing natural gas, but it owns or controls, directly or indirectly, some substantial distribution facilities. At the time we purchased those bonds, the ownership of those distribution facilities was considered an element of strength.

1090 While I was with the Equitable, it did not purchase any preferred stock or common stock. I know of no institution which has invested in any substantial amount in the preferred or common stocks of natural gas companies.

I left the Equitable in 1935 and came to Washington and joined the Securities and Exchange Commission. I was assigned to a division which at that point was not defined, but later became the Public Utilities Division. The bonds of Northern Natural Gas Company that were acquired by Equitable before I left were 12-year bonds with sinking fund provisions in the security which called for retiring practically all of the bonds before their maturity in 12 years. (Objection by counsel to the Illinois Commerce Commission.) I think I have already testified that the amount of the bonds was about 40% of the total reported value of the property. There were two or three men associated with me, and over a period of time we attempted to organize the Public Utilities Division of that Commission. During my time with the Commission, this Division grew until it was a substantial organization. Counting lawyers, accountants, engineers and financial analysts, the organization embraced approximately 100 men. I was then directing head of that Division, while I was with the Commission.

I was responsible for the administration and the personnel of that Division, and was responsible to the Commissioners as the head of the staff for the administration of the particular statute entrusted to us. It was the responsibility of the staff, under my direction, to handle all of the various applications which were filed with the Commission by registered utility holding companies and their subsidiaries with reference to the issuance of securities, acquisition of assets and securities, and all other and various matters in that rather complete regulatory law. It was our duty to analyze those applications and to prepare recommendations to the Commission with reference to approval or non-approval of the particular applications.

We had rather definite requirements under the statute, findings that had to be made in connection with the approval of the issuance of securities which under Section 7 of the Act were rather definite and specific. That section referred to such matters as whether the security bore a proper relation to the security structure of the company, whether it bore a fair relation to the earning capacity of the company, whether in general the terms and conditions of the issuance of the security were compatible with the public interest, the interest of investors, and consumers. I am quite confident that, among the security issues on which we passed and made recommendations, there were some natural gas company securities. To an extent, the natural gas pipeline companies owning only production and transmission facilities fall within the scope of the Act; although, by definition adopted by the Commission, companies which did not perform any distribution function were classed as non-utility companies.

Cross-Examination Interposed by Mr. Slaff.

The Public Utility Holding Company Act of 1938 sets out what are non-utilities, but in order to find out whether or not a natural gas company or a gas company is or is not a utility company, it is necessary to refer to that definition of a gas utility established by the Commission. That definition defines a gas utility to be a company which has facilities for distribution of gas at retail. The statute itself so states, but you have to look at the rule in order to get the proper interpretation of the term "at retail".

Direct Examination Resumed by Mr. Morgan.

1091 My duties with the S. E. C. did not require me to go out into the field and inspect the properties and operating methods and obtain other facts concerning the situation of the company whose securities were under consideration, but we did send our men out under certain circumstances. That was not the general case. It was only in special cases where such questions arose that we thought it best to send men to the field. We sent no men out with reference to any natural gas company. There were very few such companies within our regulation as a matter of fact.

The Commission itself or the staff were not required by law to establish valuations in the sense in which I think the term is being used in this case. We had no power or duty under the statute to establish valuation for rate purposes; but it is obvious that the Commission in matters of security issuance and dealing with matters in connection with the acquisition of utility assets or utility securities was required to and did look into such matters as valuation.

Some idea of the valuation would certainly be required Every release of the Commission covering the issuance of securities under Section 7 of the Act in the opinions and findings will be found to include some statement as to the assets behind the securities being issued. In most normal cases, that statement will take the form of an analysis of the property account and an attempt by the Commission to discover and locate write-ups of property or appreciation of property and such matters; in other words, the Commission attempts in such cases to find, within the limits of practical possibility, the valuations as a basis for the sound issuance of securities.

Cross-Examination Interposed by Mr. Slaff.

I would say that those valuations are more than book figures with write-ups eliminated, because the Commission had available to it in many cases historic cost studies and such matters. These are brought out in the hearings. I think we could define "book figures" as being those figures which exclude any known appreciation, write-up on the company's own books or inter-company profits and such items.

Direct Examination Resumed by Mr. Morgan.

We concerned ourselves with the earnings or the rate of return of the companies coming within our jurisdiction. In every case, in connection with the issuance of securities it was a matter of concern as to the amount of the earnings going to service the securities. The rate of return is of a different character. The Commission had no direct responsibility with reference to a matter such as rate of return as that term is used here, but the Commission in an indirect manner had some responsibility. With reference to looking into the matter of rate of return, under Section 10 of the Act in connection with applications to approve the acquisition of utility securities or assets, the Commission was required to approve the acquisition unless it found that the consideration was not reasonable and did not bear a fair relation to the sums invested in or the earning capacity of the utility assets underlying those securities. The Commission interpreted "earning capacity" as requiring some consideration of what rate of return the company was currently

earning. I think of one instance where we considered the valuation behind the securities and the rate of return and things of that sort. Mr, Booth is very familiar
1092 with that case. It was one of the early cases and one of the important cases and involved an application to acquire utility securities by the Commonwealth Edison Company, which proposed to acquire large amounts of securities of the Public Service Company of Northern Illinois, Western United Gas and Electric Company and the Illinois Northern Utilities. The acquisition was on the basis of an exchange offer, and exhaustive studies were made by the Commission in an attempt to arrive at the answer as to whether or not the application should be approved. In connection with that application we went into the subject of the rate base of each of the companies involved and the rate of return on that rate base. We came to no final conclusion for we were not required to come to a conclusion and publish our idea of the rate base. However, in arriving at the fairness of the exchange, we had in our own minds to determine whether the exchange offer was fair and in accordance with Section 10.

We were required by the Commission and it was our duty to prepare these studies in order to make available to the Commission all of the pertinent information and the recommendations so that they would have everything before them available in order to reach the proper decision. The Commission does not recommend to the public that it purchase certain securities and that they do not purchase others. The Holding Company Act imposes very definite financial standards which must be met in order to issue securities. These investigations were primarily to find out whether or not the companies who proposed to issue securities were meeting those standards. The practical effect of a refusal by the Commission under the Holding Company Act to allow a declaration to become effective or to allow the issuance of the securities is a pretty good indication that the securities are not of a quality which should be sold and made available to the public. I think the fact that such applications are approved is of some substantial influence in the minds of investors in persuading them that the securities may be desirable to purchase.

I continued in my position with the S. E. C. for two years, at the end of which I went back to New York and formed the partnership of Gilman and Hickey. We have occasion and have had occasion to devote considerable studies to the rate of return of regulated companies and such matters. Prior to our employment in this case, we were employed by other companies to perform services in the field of rate of return. In the latter part of 1938 I testified as to rate of return in a case involving the Brooklyn Rapid Transit Company. In the spring of 1939 I testified as to the rate of return in a matter involving gas rates in the case of the Rochester Gas and Electric Company before the New York Public Service Commission.

Cross-Examination Interposed by Mr. Slaff.

I do not remember the exact date of my testimony but it was in the spring of 1939 in Rochester, New York, before Commissioner Burritt. Mr. Gilroy acted as counsel for the Commission. In the summer of 1939 I testified as to the rate of return in the matter of gas rates of the Brooklyn Union Gas Company before Commissioner Van Namee. Mr. McAvoy was counsel for the Commis-
1093 sion. In the spring and summer we testified by affidavit in the matter of electric rates of the South Carolina Electric and Gas Company in South Carolina. In the summer of 1939 my partner testified in Georgia in the matter of the rate of return in the Georgia Power and Light Company.

Direct Examination Resumed by Mr. Morgan.

I assisted in the preparation of statistics and the development of ideas presented in that last mentioned proceeding.

I have been requested to make a special study of the requirements for the rate of return of defendants. I was engaged in May, 1939, since which I have devoted a substantial amount of time to this matter. I have spent a considerable amount of time in my office, considerable time in conferring with company executives and counsel, and some time in a trip over certain portions of the physical properties owned by those two companies. I visited the northern end of the properties at Joliet, the measuring and reducing station, and I visited the properties at the southern end of the line including the compressor stations at Fritch and Gray, Oklahoma. I had previously visited one or two compressor stations in the central part of the line a number of years ago. I spent some time in the offices of the company at Chicago and Amarillo, Texas. I requested certain information from company officials, such as maps, contracts and balance sheets, income statements, breakdowns of operating statistics over a period of years extending really from the start of the company's existence to the end of 1938, and certain figures covering portions in 1939. In addition to that, I studied I think it is volume 62 of the Federal Trade Commission investigation which contains a substantial amount of information about the historical development of this enterprise and its history up to the end of that study, which was as I remember 1933.

I have read the testimony of Mr. Floyd C. Brown. I chose his testimony especially because he was vice-president and general manager of the company and a man with whom I had talked. I felt that his testimony, being general in character and primarily devoted to such things as the development of the enterprise and its present status in the field of natural gas supply, would provide me with certain information which I should have and which probably could be obtained in that way better than by addressing to him a series of questions or a questionnaire. I also talked with the general superintendent and other executives concerning the mechanical and engineering problems with which defendants have had to deal and are now dealing. I talked particularly with Mr. Kesinger about such matters. I submitted a list of information where I felt I needed to have it, and I was furnished everything that I asked for. I have gone into other sources of information besides the records and properties of these companies in determining what ought to be the rate of return for them. In forming my opinion as to a proper rate of return for such companies as these I would rely primarily upon my background and experience in financial matters, having been in that field for a great many years. However, I should and have always given such cases study in connection with certain statistics and financial data for use primarily as a check and a guide on the results.

1094 (October 4, 1939.)

I prepared a summary of certain parts of the study I have made in this connection. I have not included everything I gave consideration to, of course, but certain parts of that study I have set down on paper in a document captioned "Natural Gas Pipeline Company of America and Texoma Natural Gas Company, Data Concerning Rate of Return, Witness, W. C. Gilman".

(At this point counsel handed to the reporter the document just described, with the request that it be marked for identification. At the direction of the Examiner, the document was marked Exhibit 150 for identification.)

Exhibit 150 contains financial data of various types which I considered of some importance and value in checking my judgment as to a proper rate of return for a company such as defendant.

On page 1 is a tabulation of natural gas company bonds, showing the bonds of eight natural gas companies. We show the price of the bonds at September 15, the latest available date, and the yield to maturity as of that date.

On page 2 I show a tabulation of gas company common stocks. I think the language explains what this page tends to portray. Page 3 shows a list of all mortgage bonds of domestic electric and gas utility companies traded on the New York Curb Exchange September 15, 1939. Page 5 shows a statement of preferred stocks of electric and gas operating utilities listed on the New York Curb Exchange.

Page 6 and succeeding pages to 15 show a tabulation entitled "Rate of Return on Invested Capital for a Large Number of Industrial Classifications".

The sheets from pages 7 to 15 being the supporting data for the material shown on sheet 6.

The chart at the end of the exhibit shows the average ratio of earnings to market prices of 12 operating public utility common stocks compared with the average yield on 10 high grade utility mortgage bonds rated by Moody Aaa.

Cross-Examination Interposed by Mr. Slaff.

Pages 7 to 15 show the companies making up the category of the companies on page 6.

The data supporting a return of 6.88 on invested capital for Automobile Parts and Accessory Manufacturers would show the invested capital for each of the companies, a total invested capital for all of those companies, and the return expressed in dollars for each of those companies and for all of those companies. That is
1095 found in my work sheets. The original sources were the Form 10 reports of these companies to the Securities and Exchange Commission. Practically all the American companies who have securities listed on the National securities exchanges are included in this rather wide cross section of American industry. As I say, the primary sources were the Form 10 reports to the Securities and Exchange Commission, but they were collected together, and my actual source is from a study at the Securities and Exchange Commission of those Form 10 reports. A separate study was made of each particular industry. An example of one of these studies is that of the Chemicals and Fertilizers entitled, "A Partial Report of the Census of American Listed Corporations. A Works Progress Administration Project Sponsored by the Securities and Exchange Commission". They have gotten out some 36 of these reports already. I have included every one that has come out.

Cross-Examination by Mr. Morgan Resumed.

Turning back to page 1, I tried to select eight companies which were typical of this industry, to some extent comparable with the companies under consideration. I obtained the prices of the bonds at September 15, 1939, and from that calculated the yield to maturity on those bonds. It will be noted the yield to maturity is with some substantial variations, extending from somewhere around 3 percent to something over 5 percent. It is indicative of the prices and yields to investors from natural gas company bonds outstanding in the hands of the public.

On page 2 are listed 16 companies. There are natural gas companies and there are also listed here a number of companies which furnish mixed and artificial gas service, because I believe it is desirable to show some of those companies. This page shows the earnings price ratio at which the common stocks of those companies are selling. It will be noted that the earnings per share

are the latest reported for public information, the market price was as of September 15, and the third column was obtained by dividing column 1 by column 2 to obtain the earnings price ratio. It shows simply that some companies' stocks are selling on as low a basis as 6.51 percent, and that other company's stocks were selling on as high as a 14.0 percent basis.

Questions by the Examiner.

It was not possible to use the same gas companies listed on page 1 for the purposes of those listed on page 2 for the reason that a number of those companies listed on page 1 have no common stock outstanding in the hands of the public. That was the only reason for omitting them. As a matter of fact, one of the difficult things in this case, is to find a sufficient number of securities on which to formulate a judgment. I think I have a sufficient number to do so, but it is a fact that there are not many natural gas pipeline companies as compared with electric companies or gas companies on which to make comparisons which are ordinarily made in the financial world in trying to appraise securities. I made no comparison of this list with Mr. Emery's list. Mr. Emery's list had to do with annual figures to the end of 1938. These figures are up to September of this year.

1096 Another thing that I should call to the attention of the Examiner is that some securities have been sold privately probably since Mr. Emery's exhibit was prepared, in which case it is impossible to get a quotation and therefore impossible to obtain a yield. I think the El Paso Company, since the end of 1938, has refinanced on a private basis. With respect to the Southern Natural Gas Company, I designate the issue as first mortgage sinking fund 4½'s. That is the same issue designated by Mr. Emery as first mortgage bonds 4½'s. I do not include the Adjustment Bonds or the Alabama First Mortgage Issue of 1951, which is shown on Mr. Emery's list. In my judgment I included the bonds best suited to portray what I wished to portray. The Adjustment Mortgage Bonds are another issue of bonds of the Southern Natural. I felt that the first mortgage issue was most indicative for my particular comparison.

Cross-Examination by Mr. Morgan Resumed.

I have not compared my data with that of other witnesses. I have not seen their exhibits and they have not seen mine.

Page 3 shows a list of all mortgage bonds of domestic electric and gas utility companies traded on the New York Curb Exchange on September 15, 1939. In my opinion, these companies here are in competition for capital with other electric and gas utility companies, and in fact with all industry in the United States. They can only attract capital and can only maintain their credit if their earnings or the rate of return on their fair value is maintained in such a manner as to support their credit standing. Investors do not go out looking for the lowest yield they can find. On the other hand, they go out and look for the highest yield that they can find, commensurate with safety. In other words, they are looking for a product of the yield multiplied by safety to reach a maximum figure. The thought that investors go out looking for the smallest yield is not borne out in the practical world. Investors are looking to the high yield, and that is one of the reasons why I have prepared this exhibit. It shows a rather wide list of electric and gas utility mortgage bonds which were traded on a national market, the New York Curb Exchange, and to that extent it is a non-selected list. It included all of the bonds traded on that Exchange during that day, covering utility companies all over the United States.

The yields obtainable vary all the way from 3-odd percent to as high as 9.57 percent, with an average yield on the whole list of 5.12 percent, which is some indication that some investors could at that date go out and invest in a diversified list of mortgage bonds of electric utility companies and gas utility companies and perhaps obtain a yield of as high as 5 percent.

Similarly, page 5 shows a list of preferred stocks of electric and gas operating utilities listed on the New York Curb Exchange. I have included in this list all of such companies which had outstanding any substantial amount of such stock which has fair marketability. There are some 35 companies, and the average yield on the whole list is 6.4 percent. That average does not show on the page but I have calculated it. It is the straight arithmetic average of the yields set out in the final column on page 5.

That is true also of the average yield of 5.12 stated for pages 3 and 4.

1097 Page 6 shows that for the years 1934, 1935, 1936 and 1937, and the average for those four years where available, the average from 1935 to 1937 when the 1934 figures were not available, computed as shown in Note 2 at the bottom of the page. The averages for the units used are again a pure arithmetic average. Those lines are not the names of firms, but classes of industry. For example to explain one of them, the Automobile Parts and Accessories Manufacturers shown in line 1, it appears that a return on invested capital in 1934 of 6.88 percent was earned. The earnings in 1935 were 13.82 percent; in 1936, 16.50 percent; in 1937, 15.2 percent; and the average for the 4 years, 13.10 percent. These figures are obtained by studying the reports of a large number of companies who go to make up this industrial classification. There are approximately 42 companies who are listed on page 7, which include all companies of any importance who had securities listed on National security exchanges. They are the same companies that the S. E. C. in their reports to which I referred a whille ago used as the basis of their computations.

Questions by the Examiner.

I could only estimate the proportion of the total industry in the country that have securities listed on the Exchange which are represented by this compilation here on page 6. The only American industries excluded from this are the regulated industries, the Public Utility Industries and the railroads, and a few other industries, such as the hotel industry and service industries of that character. The list, it will be appreciated, is a very wide list, covering practically all of American industry. It was my purpose to get the widest cross section, the widest appraisal of what capital is earning in American industry, because I think it is of some importance in consideration of a problem of this kind.

We have to adopt some kind of a statistical method, and it gets down to a question of a degree of accuracy. It is possible that a finer result would have been obtained if we had taken the net operating result for each months' period divided by 12 and going along by that method we could do it for each day of the year. It gets down to a question of refinement. I think for the broad purpose and for dinary statistical purposes the method employed here is the common one. I should call attention to the fact that while it is stated here, I want to make it clear, that this rate of return is before income tax.

Direct Examination Resumed by Mr. Morgan.

The chart at the end of the exhibit shows by the bottom line Moody's 10 public utility bonds Aaa class, which is the standard or one of the standard indices of yields of high grade bonds. It is published monthly and available in all the services. It shows an almost continuous downward trend in the rate of interest yield to investors on high grade public utility bonds from 1932 down to September 1, 1939, when it will be noted that there was a substantial upward movement. Of course, everybody realizes that at that time there was a substantial upward movement and high grade bonds declined rapidly in price.

This, as I say, is a standard index. I had nothing to do with its preparation. I simply adopted it as being an indication of the movement of high grade bond yields.

1098 There is no such index of public utility or electric and gas utility common stocks. I felt it desirable to construct such an index, and this index above the bond index has been prepared. That has been made up of 12 operating utility common stocks, and shows quarterly during the period the ratio of earnings to prices during that time. While it will be noted that the bond yield has shown almost continuous downward movement, there has been no such similar parallel movement of earnings price ratio on utility equity stocks. In fact, the movements have been at times quite violently opposed, and the earnings price ratios of the stocks are substantially above the yields on the bonds and are trending upward at the end of this curve. The companies selected were considered to be 12 of the outstanding electric and gas utility companies in the country. Those included were the Boston Edison Company, the Cleveland Electric Illuminating Company, the Commonwealth Edison Company, The Duke Power Company, the Hartford Electric Light Company, the Southern California Edison Company, Ltd., the Consolidated Edison Company of New York, Inc., the Consolidated Gas and Electric Light and Power Company of Baltimore, the Pacific Gas and Electric Company, the Detroit Edison

Company, the Brooklyn Union Gas Company and The Peoples Gas Light and Coke Company.

The earnings price ratios shown on the chart are established quarterly, that is the earnings available for dividends as the result of the given year's operations are related to the average of the high and low market price of July and October of the same year, and January and April of the following year.

That is another well known statistical method. As a matter of fact, I originally ran into it in a Federal Communications Commission study of the theory that investors' appraisals of securities at any particular time are to some extent based on the past earnings of the company and what their expectation of the future earnings of the company is. So we equate the earnings say of 1939 to the price which existed, the average high and low, of January and April, 1940, where those fellows were anticipating the 1940 earnings, and in July and October of 1939 where ostensibly the earnings were available to them, and they knew what the earnings were and could so adjust their price ideas. The printed figures on the left margin of the page shown on the chart are meaningless. The only figures that mean anything are the figures on the right and on the left, denominated 1.0, 2.0, 3.0, and so forth, which means percent. In the case of the bond yield, it is the yield in percent. In the case of the stock index, it is the earnings price ratio, a percent. This exhibit was prepared by me and under my direction.

I have checked the exhibit and adopted the figures as my own.

(EXHIBIT 150 was offered in evidence.)

Questions by the Examiner.

The four points on the common stock graph, as applied to the year 1938, were so determined because the results for the 12 companies are obtained by taking the result for each company in turn, adding them together and then dividing by 12. Let us take the first company, the Boston Edison Company, for 1938. From the report of that company we find the earnings available for dividends on the common stock on a per share basis. I did not have the figures but they are shown in the annual report of the company to its stockholders for the year 1938, or they can be found in Moody's Manual, which is considered an official financial document.

1099 All of these companies make their fiscal year correspond with the calendar year. In any event, in every one of the cases here, we have obtained an earnings figure for the calendar year end. Then with that one figure of earnings per share established, we would find four prices of this company's common stock by referring to such financial data as the Commercial and Financial Chronicle, the Bank and Quotation Supplement, and possibly the New York Times for the daily quotations. I said four figures, actually for the month of July and for the month of October, 1937, we would obtain the high and the low price of that stock during each of those months, and would add them together and divide by 2 to obtain the average price at which the stock sold in July, 1937 and the average price at which the stock sold in October, 1937. Then we would do the same thing for January, 1938 and the same thing for the month of April, 1938. Then we would have four prices established. We would then take those earnings which we had previously found for the year 1938 on a per share basis and divide those earnings in turn by each of those prices; namely, for July and October, 1937 and January and April, 1938. That would establish four earnings price ratios, one for July, one for October, 1937, and one for January and April, 1938. Then at this particular point, I should say first of all, since we are only dealing with one company now, we have to combine the 12 companies, and then having obtained those figures for those particular months, put them on the chart. The straight average is arithmetical and not weighted.

For simplicity purposes in preparing the chart, the established earnings price ratio for July is set right in the middle of the year 1938. That method was pursued consistently throughout the four quarterly periods. Again it comes down to a question of refinements. Possibly for more extreme accuracy, the figures should have been half way between June and July, but in matters of this kind I do not think that is essential. This chart was prepared to show the ratio of the relation between high grade bond yields and the earnings price ratio on high grade utility stocks to indicate a substantially wide spread.

The bond curve was Moody's Public Utility Bond Index AAA of public utilities. I think actually it is prepared by Moody monthly for their own purposes, and in order to have some similarity here, I have plotted it quarterly. You will see by the way the chart moves, that the line at the beginning of 1937 goes in a straight line. In other words, where Moody's had a curve, I had a series of straight lines. Moody would have a smoother curve, though it would not be a curve because they only do theirs once a month. Of course, if you do it once a day, you have probably a smooth curve. The reason I stagger my earnings and average high and low prices is that the earnings price ratio itself is an indication of the investor's appraisal. In other words, it is earnings divided by the price. It tells what the investor is willing to pay. A common method of talking about that sort of thing is to talk about the price earnings ratio, which is the reciprocal of the other, and I think it is perhaps more commonly known. People will say they would pay seven times the earnings for stock, or 10 times the earnings for stock. It is a direct appraisal of the market by the relationship of the earnings. In other words, we use our July and October, 1938 price figure with our earnings figures, because there is a market relationship.

I probably did not make it clear as I originally stated it. My theory, and I think the well established theory is that the people who are buying stock today and who are establishing price for stock today by their orders to buy stock, are buying the stock of a particular company with 1100 several thoughts in mind. They have seen the latest Annual Report, they know what the company earned historically. Also, they are buying on what the company is going to earn because they have some idea or some information, or think they have, on what the company is going to earn in 1939. Therefore, the truest measure of this thing is by having this earnings price ratio calculated this way, rather than always on the basis of hindsight.

If we tried to do it any other way, we would be up against the proposition in 1939 of working on 1938 figures. I think it is well known in 1939, September 15, conditions are quite different that at the time those earnings were established during the year 1938. Industrial activity in this country is at a much higher tempo today than it was in December, 1938 and during that year as a whole. So in order to obtain a fairer measure of the appraisal of the equity, this method has been adopted which attempts to combine in this chart, ideas of hindsight and foresight. There are other factors in addition to earnings, which determine market price, but this contract only uses and only establishes the relationship between earnings and price over the period.

Direct Examination by Mr. Morgan Resumed.

There are hundreds of factors which go to make up the price. The price is established in the minds of investors and with the investors all over the country. All such matters and everything that could be thought of enters into such things. The public's appraisal of those elements is wrapped up in the price which the public is willing to pay.

Cross-Examination by Mr. Slaff.

The reason I used the average price for one month out of each quarter instead of the average quarterly prices for each of the four quarters is that I wanted to obtain that relationship four times a year. This method will show you more rapid fluctuations, which I think should be done, than by adopting the average price of any quarter. I do not agree with you that a more accurate appraisal of the showing would be by taking quarterly high and low averages. I think we are getting away from that. The old-fashioned way of doing this would be to take the average of the high and the low for the year and equate that to the earnings for that year. I think that was from a statistical point of view improper. I think we have gone far in advance of that, and this method is much better. The reason I do not go still one step further and take the high and the low from July 1 to July 15 is there comes a question of degree in all statistical methods, where the additional refinement is not worth while in view of the results to be obtained. I want again to emphasize that this chart was not prepared primarily with any thought in mind of establishing any point of departure and saying that the utilities' stocks are worth about twelve to fourteen times earnings; that is, high grade utility companies such as included in this chart.

The chart was prepared primarily, as I said before, to show the relationship in the movement of utility high grade bonds' yields in comparison with earnings price ratios on common stock.

For your own information, Mr. Slaff, I will say that this method was the method which was developed primarily

originally by the Federal Communications Commission in their study of rate of return which you have
1101 available; and I felt that it was such a good method of presenting the data that I adopted it. As a matter of fact, they prepared a chart practically like that but they included some telephone companies, which I excluded from this particular list because I did not think it was pertinent at all. I am referring to the study that was prepared under Mr. Wheat's direction.

Cross-Examination by Mr. Booth.

The calculations on pages 6 to 15, inclusive, showing the percentage earned on invested capital were made by the Securities and Exchange Commission W. P. A. project. However, I had checked at the New York Stock Exchange a sufficient number of these calculations from the original sources to satisfy me that the compilations are correct. I made no calculations as to what the rate of return on the invested capital would be after payment of income tax. I would not say that I have no idea what the return would be on any of these corporations after the income tax deduction. It would be somewhat smaller. For purposes of comparability, in comparing a large number of companies of this kind, I understand it was not possible to make the comparison after income tax. I know that in the determination of public utility income for rate-making purposes the income is computed after the payment of income tax and other expenses. I know how this calculation was made and it is explained in Note No. 2, the net operating results, and I personally have checked some of them myself to determine exactly how the net operating result was obtained.

I was going to make absolutely clear in the record that particular point of the income tax. You will note that Note No. 2 says: "Computed by taking the net operating result for the period before interest and prior claims and income tax." That is, before interest, before prior claims, and before income tax, and dividing this amount by the total invested capital at the end of the period. It is obvious that nobody could determine whether or not the items of depreciation and depletion have been adequately taken care of before the net earnings were computed. I made no study to determine that. These figures are from the sworn reports of the companies. I do not know what each particular company did with respect to depreciation in any particular year, but I have been over the reports and have noted the item of depreciation at that time. I would not be in a position to state that any company in the United States or in the world had in a particular period taken the proper amount of depreciation and depletion without a careful study.

You asked as to whether or not it is my opinion that an investment in, for instance, the business of the snuff manufacturers would be attended by a risk comparable to an investment in the Natural Gas Pipeline Company of America and Texoma. It is my opinion that an investment in a well selected American snuff company would be a more safe investment than an investment in the Natural Gas Pipeline Company of America. As a matter of fact, the Equitable Life Assurance Society, with which I was associated, had substantial investments in an American snuff company. I think you made a bad selection, because the statistics of the snuff industry in this country are rather amazing. I will say that the statistics for the snuff industry show a degree of stability which is at least equal to that of the natural gas industry in this country.
1102 I would not attempt to compare a particular industry in so far as any one of the fifty points of comparison that might be made to the particular companies involved here. In matters of this kind, while the Bluefield case definitely said, "Investments of the same character and of the same degree of risk must be used," from the practical financial point of view they did not say anything that investors for years have not always had in mind, what other industries are paying, and they would only put their money in these regulated industries if they could obtain a higher return in that industry commensurate with the safety they wanted. So, from the standpoint of economic principles, the Bluefield case did not do anything. I would not attempt to compare any particular company with these companies here, but the very breadth of this list covering all American industry, practically, outside of the regulated industries, gave a measure of what is being earned in other industries at the same time, and that is the only way to get such a measure.

I have not, on paper, made any comparison of any of these businesses with the business of defendants. I have been in the investment field and been responsible for the investment of large sums of money for a great many years.

In the processes of my mind, I am always automatically making comparisons. I have told you I did not make a comparison of the risks of the companies shown in this exhibit on page 6 and the risks of investment in defendants.

Direct Examination by Mr. Morgan Resumed.

The figures shown on pages 6 to 15 of Exhibit 150 simply put down in one place in tabular form what capital is earning in other businesses. Anybody in forming an opinion as to a proper rate of return must know these figures. He may not do that exactly in this way. He may not have the figures in exactly this shape. He may have them in some other form, or he may have other tabulations made, but anybody forming such an opinion must have an opinion as to what capital in other industries is earning. The conception of a fair and proper return must be taken into consideration in connection with the competition for capital. Regulated industry companies, such as the pipeline companies, only can get capital and their credit will only be maintained if they stand well with investors and are able to offer investors a rate of earnings which, combined with safety, is better than generally obtainable from other industries, and to that extent I used this compilation here. In my thinking, I did not rely solely on this exhibit nor any other exhibit as of any great weight, but in forming my opinion on rate of return I rely generally on my knowledge of the financial world extending over a number of years. The facts set out in this exhibit are a part of my general knowledge.

There were three snuff companies used in making up the line on page 6. Now, in the use of the term "comparable", it is not necessary that the companies compared be identical in all respects. "Comparable", in my understanding, means things that have characteristics, which are similar or dissimilar; that is, characteristics which are capable of being compared. If I had the time I would appraise the risks confronting these two pipelines companies and
1103 make up my mind whether it is more or less a risky enterprise than any one of these groups of industries listed here. But I have not used this as a basis for saying that these companies are entitled to a certain rate of return because the automobile manufacturers were making 22.03 percent and the snuff manufacturers something else, 13.98 percent, and the beverage manufacturers 37.69 percent. As I said when I made my original explanation preliminary to all of these exhibits, I have simply used this as a form

or guide or check on my judgment in the conclusion as to which I came in the matter of a proper rate of return for these two pipelines. In my opinion, it is not possible to find any other natural gas pipeline company or any other industry in the United States, which would have absolutely the same risks in every particular as the risks which have confronted and which do confront these two particular companies.

Cross-Examination Interposed by Mr. Slaff.

I do not think the word "corresponding" has the same meaning as the word "comparable". I do not see any connection between the two. As I understand the word, "corresponding" means something which resembles. However, when I use the word "corresponding" I mean two things which resemble each other in a general sense. (Objection by counsel to Illinois Commerce Commission taken under consideration.)

Questions by the Examiner.

As I stated earlier, it would not be possible to go through and make the calculations on the companies listed on pages 6 to 15 of this exhibit after deducting the income tax, and, of course, it would be utterly impossible for the Federal Power Commission to calculate proper depreciation, as counsel calls it, on those companies.

Cross-Examination Interposed by Mr. Slaff.

I used the securities listed on the New York Curb Exchange on pages 3, 4, and 5 rather than the utility securities listed on the New York Stock Exchange because the latter is very narrow. There is a much more representative list on the New York Stock Exchange. I did not bring those listed on the New York Stock Exchange into my computations at all. I thought that I had enough. I selected the New York Curb Exchange as giving a representative list.

Direct Examination by Mr. Morgan Resumed.

In connection with my examination of the properties and records of defendants, the reading of the testimony of Mr. Brown, and in the light of my knowledge of the natural gas industry and the Natural Gas Pipeline and production industry, I have a judgment or an opinion of the character of the risks and hazards that have confronted and which now confront defendants, as those risks and hazards are viewed by investors. I have made use of this judgment in arriving at the conclusions which I will later express as to a proper rate of return for these companies.

I am and have been for a long time familiar with the
character of ordinary electric utility business, and the
artificial gas utility business. I have been continuously
engaged for more than ten years in daily contact with
problems involving utility securities and matters of utility
financing. In connection with this study, I have given
thought to the comparative safety or security of investment
in the ordinary continuing utility and in a natural gas pipe-
line company engaged in the producing and transmitting
of natural gas. I do not think there is the same
1104 degree of safety and security in an investment in a
natural gas pipeline company security backed up by
production and transmission properties as in the ordinary
electric utility field. The natural gas pipeline and produc-
tion industry is a more risky industry from an investor's
point of view. I must speak generally. There may be
some small or medium sized or even large sized natural
gas pipelines which in a particular case are better than
some electric companies which happen to be in receiver-
ship at the time. I am simply emphasizing that I am
speaking generally, and I say that generally the electric
industry is a much safer industry from an investor's point
of view than the natural gas industry. I base that state-
ment upon my long continuing study and observation of
the electric industry, and a study of its investment charac-
teristics, and the study of the results of many hundreds of
companies, and a continuous attempt to appraise, as all
people who are responsible for the investment of funds are
responsible for appraising, their risks. That is the ap-
praisal of the public in dealing with securities and the
valuations placed on these securities as compared with
securities by a natural gas pipeline company.

As between an electric utility and a utility distributing manufactured gas as a class, my opinion is that as a class the electric utility industry offers greater security than the manufactured gas industry. I say that because I am familiar with the characteristics of an electric industry. That industry as it exists today has at least, insofar as its domestic market is concerned, a practical monopoly in service which it furnishes. Nobody is competing or can compete with the use of electric energy in the home, with the great number and increasing number of appliances for utilizing electric current. The output and consumption of electric energy are generally increasing from year to year. Similarly, in other fields the electric industry, generally speaking, is making over a period of years good advances. The gas industry, however, as an industry, is not in any such position. For a number of years the gas industry has been suffering in competition and has lost substantial amounts of its domestic business. Investors at the present time are somewhat skeptical of the future of the manufactured gas industry. They are not sure where it is going.

Electricity was first used in the American home for lighting purposes. At the present time it is used in the home in a countless number of ways. There are myriads of numbers of appliances which are available to the householders, reasonable in price and offer great convenience to the householder, and consequently they have had rather wide public acceptance with consequent good results for electric companies. Some of the common appliances which every home has are the ironer, the toaster, the coffee percolator, the fan; and then getting to the larger appliances, in some cases, the washing machine, in some cases an electric water heater, air conditioner, electric blanket, and a new appliance which has recently come into great prominence in a very large scale is the electric roaster, of which some several hundred thousand will be sold this year, and which will come into homes, and will to the extent that those homes now have gas service reduce the consumption of gas because they will be used once in a while. They probably won't be used every day for cooking, but the device is such a satisfactory device from the housewife's point of view, from the standpoint of convenience, that she will use it to cook a meal once in a while. They just put the food in the roaster and turn on a key which automatically turns off when the meal is roasted. That sort of a device is a device which offers some substantial hazards to the gas company in the territory wherever one is sold, and automatically results in an expansion of
1105 electric energy consumption. I did not mean to overlook the electric sweeper and electric refrigerator. Of course, the electric refrigerator is one of the most important electric appliances.

The manufactured gas business is to a great extent in competition with other fuels and other methods of doing the same job. All the manufactured gas industry provides is a heating service. It delivers to you B.t.u.'s for which you pay dollars. It can only and will only be able to continue furnishing those B.t.u.'s if it can bring those B.t.u.'s to you cheaper than you can get them anywhere else. Such things as oil, and, in certain cases, such things as solid fuel are in direct competition for heating purposes. I have already stated that the electricity is in competition so far as the use in the kitchen is concerned.

Let us go one step further and introduce the distribution of natural gas, by which I mean an owner who has provided himself with the facilities for distributing natural gas only, but does not own the production and transmission system. I mean to compare the manufactured gas industry which manufactures and distributes gas with the natural gas distributing company which purchases its natural gas from others, and does not own its production and transmission facilities. From a short range point of view, many investors would be inclined to regard the company distributing natural gas and obtaining the gas under contracts as being a desirable sort of a thing, inasmuch as the company is in a position today to sell B.t.u.'s at a cheaper price; but from a long range point of view, conditions may be quite different. If the natural gas company which is purchasing and distributing gas is confronted with the failure of its supply and it has to go back into the manufactured gas business, and perhaps build plants or something like that, it will be faced with the difficulties of rate increases in all probability, and all of the difficulties which go with that change back from a high heat gas to a low heat gas.

This change back is an extremely difficult thing. Once the customers are expecting to receive the natural gas of, say, 1,000 B.t.u. heat content at so much per thousand feet, and they are changed back to manufactured gas with some 550 B.t.u. heat content at somewhere near the same rate, they are paying about the same money for half the heat. They do not like it. A company having to undergo such a change would probably go through a financial crisis unless a public service commission acted with great promptitude and with greater promptitude than they ordinarily act. We have had several cases of that kind already in this country, and substantial financial hardships have been encountered.

For example, in Elmira, New York, the gas company has had to change back and forth from natural to artificial gas and vice versa a number of times. In fact, it has changed so many times it is difficult to keep track as to which kind of gas they are using there. They were originally a manufactured gas company and then they went to natural gas because that became available. The natural gas supply failed absolutely and they had to rebuild and put in manufactured gas plants. A few years ago natural gas again became available from the Tioga fields in Northern Pennsylvania and natural gas is now being served.

The City of Chicago has undergone the same experience in its past history. At one time in the '90's, at the turn of the century, there were substantial pipelines running into Chicago supplying natural gas to the gas companies
there from the Indiana fields. Those fields were in a
1106 very few years exhausted and the supply completely
failed. The result was that the users of that natural gas had to go back to artificial gas.

Going one step further, let us compare the risks and the security of a natural gas pipeline company which owns distributing properties only and which purchases its gas from some other source, with what has been referred to here as an integrated company—a company which owns production and transmission facilities for producing and transmitting its own gas and its own distributing company.

In my opinion, generally speaking, a company having a natural gas distribution system is a safer and a less risky investment than an enterprise which has a pipeline connected to a distribution system, so-called integrated enterprise.

This is because from an investor's point of view, generally speaking, the safest form of an investment is to have an investment in the facilities which are used for distribution at their point of use. The distribution system includes the pipes and the mains laid in the street, the services and the meters running right into the house. They will probably be used for many years to come, whether artificial gas or manufactured gas, or some new gas that should be invented is used. It is probable that those pipes have long life in the streets, already laid, and will continue in use for many years to come, and therefore will be of use. No one can tell, generally speaking, with respect to the life of a pipeline which runs from a particular field, or even a particular group of fields, to a particular spot, and their sales of gas. With the failure of the gas supply at the supply end, the pipeline is, from an investment point of view, a loss; and to that extent an investment in the distribution facilities alone is regarded as a safer type of investment than in the one where pipeline and distribution facilities together are owned. As a matter of fact, a natural gas distributing company, if the source from which it is purchasing its gas should fail, always has the possibility confronting it that it might be able to purchase gas from some other source. And if there be no such source available, it can always turn, as I have observed, back to the distribution of artificial gas.

If the source of supply should become exhausted as in the case of the integrated company which owns distribution facilities also, there is always the possibility of saving for permanent use a part of the investment that is used in the distribution end of the line, and only a part of the total investment is lost by reason of the failure of the supply; namely, the investment in the production and the investment in transmission facilities. If this integrated company be compared with a pipeline company which owns production and transmission facilities only, it appears that an investment in the integrated company is a safer proposition than one in the company which has no control or owns no distribution. I heard the statement of Mr. Delafield on that point, in which he stated at some length the advantage of owning the distributing market facilities. I am in agreement with that observation but I did not form my opinion from hearing Mr. Delafield's testimony. That is my independent judgment and was my judgment before I heard Mr. Delafield testify.

1107 There are other reasons why securities of an integrated company offer a safer and more desirable security from the standpoint of the investor than those of a company owning only production and transmission facilities. Any company which owns distribution facilities or controls distribution facilities can save a part of its investment if the production goes sour and the pipeline is abandoned. The distribution system usually represents a substantial part of the total investment. It might be 50 percent of the total investment. This part of the investment, as I have already observed, will continue in use for furnishing heat in gas form to customers insofar as we can see ahead today; but that is not the case with reference to the transmission system from the source of supply to the place where the distribution system takes up, because they have no distribution system.

Among those companies owning only transmission and production facilities, a distinction obtains in the case of those companies which rely solely upon one source of supply as opposed to a number of sources of supply. An investor would naturally, other things being equal, consider the company which had a multiple source of supply as being a safer investment than the company which relied on a single source of supply. When I speak of all other things being equal, I am excluding supply. The fact that a single source of supply might be a large one might change the degree of the hazard on that point but it would not remove it. The hazard would still be there. It would be a greater hazard with one source of supply than a multiple supply, assuming that the multiple supply were reasonably adequate for the particular job at hand. However large the supply, it will last just as long as the total quantity divided by the total removal will permit it to do that, and it depends altogether upon who all are taking and how much as to how long it is going to last. Of course, a single source of supply from which a number of companies are taking gas represents a more risky situation than would one where a single source completely under the control of the company in question exists.

I would like to make my position clear on the question of a single or scattered source of supply. My position is this: An investor considering a pipeline which had only one source of supply would be somewhat fearful of the failure of supply in that field, whereas if this company had contracts to purchase gas from four or five fields and was obtaining gas from four or five fields with a multiple source, it is a less risky proposition. It is an application of principle of diversity. If one of the fields failed, the other four would be left, if there were five sources of supply. I have assumed in each instance that there were a number of owners who were producing on the same sources of supply. That is the situation in practically all of the fields from which natural gas is being produced.

I think my memory is sufficient for me to state the companies on pages 1 and 2 of Exhibit 148 which have more than one source of supply. The El Paso Natural Gas has one source of supply. The Arkansas-Louisiana Gas Company, the Columbia Gas and Electric Company, the Lone Star Gas Corporation, the North Penn Gas Company and the Panhandle Eastern Pipeline Company all have more than one source of supply. The Southern California Gas Company and Southern Counties Gas
Company have more than one source of supply, if
1108 my memory is correct, and I know that the Southern
Natural Gas Company has only one source at the present time, the Monroe field. Turning to page 2, the El Paso Natural, Republic Natural, Southern Natural, Mississippi River Fuel, Memphis Natural, each has only one source of supply. The Oklahoma Natural Gas Company, Mountain Fuel Supply Company, Columbia Gas and Electric, Lone Star Gas Corporation and the National Fuel Gas Company, each has a number of sources of supply. I am not sure as to the Pacific Lighting Corporation, but I think it has a number of sources.

Cross-Examination Interposed by Mr. Slaff.

The highest earnings price ratio of the common stock as reflected on page 2 is that of the Oklahoma Natural, which has a number of sources of supply. Referring to bonds shown on page 1, the highest yield 5.24 is for a company, the North Penn Gas Company, which has many sources of supply. But you cannot put these things absolutely in slots. In generalizing and answering questions as to the degree of risk, you must say generally what you believe.

Questions by the Examiner.

The companies shown on page 2 with their common stocks are listed, some of them, on the New York Stock Exchange, some on the New York Curb Exchange and some over the counter. The companies like the Providence Gas Company and Springfield Gas Light Company are not listed on the Exchanges. The stock of the Oklahoma Natural Gas Company is held publicly.

Direct Examination by Mr. Morgan Resumed.

In going over the comparative safety and security of investments in different types of utilities, and in the natural gas pipeline companies, this morning, I was stating the comparative risks of those industries in general as a class. It should be emphasized that any particular company in any one class may have a different risk from that class as a whole. I have known electric companies which have the highest order of risk of any of those considered getting into bankruptcy. As between bonds and preferred stocks of the same concern, the bonds are the senior security, and of course have the lowest degree of risk. As between the two classes of stock, preferred and common, of course the preferred stock is senior and is the higher order of security. The common stock is the riskiest type of security. Investors would not buy the bonds of a natural gas pipeline company extending over the entire period of the indicated life of the source of supply of natural gas. The investors would wish to buy a bond which matured and was paid off some years certainly before the end of the projected life. The purchaser of stock in taking the risk involved would demand his price. He would demand a yield sufficiently high to compensate him for the risk that the supply would terminate prior to the time indicated. That is the only way he can be compensated for that risk, is by getting a higher rate. He has an investment in the residual earnings of the enterprise after the bondholder and/or the preferred stockholder is paid. He has the riskiest position. If any miscalculations are made, he is going to suffer because he is on the tail end. In other words, if the risks are such that the owner of the superior security gets hurt, the stockholder is counted out altogether.

1109 There are other risks confronting the pipelines involved in this inquiry which I think would enter into the value of their securities if offered to the investing public. Any natural gas pipeline company which produces and/or purchases natural gas and transports it through a line for sale is subject, of course, to the principal hazard of the possibility of failure or shortened life of the supply. Under ordinary circumstances, a project of that type would be engineered and financed from an economic point of view on the basis of a definite life and assured life. If there are any mistakes in those calculations and the life is shorter, investors may suffer. The possibility of error one way or the other is something that definitely must be taken into consideration by investors who are considering the securities. From the investor's standpoint, there is a hazard as to the amount of additional capital investment which will be required, but I would not place that in the No. 2 position. To go ahead and enumerate the risks as I see them in the natural gas pipeline producing and transporting companies, the primary risk is the risk at the supply end. In my opinion, of second importance is the possible risk at the other end, depending upon how the gas is sold. If the company contracts for the sale of all of its gas and has no control of its markets and owns no distribution facilities of its own of any kind and controls no distribution facilities, that is a risk which investors would very definitely evaluate in considering the securities of such company.

Other risks which should be taken into consideration and would be taken into consideration by investors at the present time are such matters as regulation. Regulation under a new law which nobody knows anything about, nobody knows how it is going to work.

Other risks which to some extent are common as to other public utility companies in greater or less degree are the risks of rising costs, with fixed contract prices for your output, rising expenses for labor, materials used in the maintenance and the ordinary operation, and taxation.

Particularly, investors will take into consideration taxation when they have observed a tendency on the part of many people to urge taxation on companies of this kind on a two-cent per thousand cubic foot basis, where the taxes might be rather easily assessed. Such factors are hazards which investors are bound to and would take into consideration in arriving at whether or not they would be interested in the securities or the price which they would pay for them. In the emergency, or the so-called emergencies which have existed during the last 10 years or so, the public utility companies as a class, electric and gas utilities, have certainly had to stand their share, or more than their own share, of the special taxation to meet budget deficits. I know there is a very vociferous public opinion which is asking for the taxation of natural gas. The miners' groups and groups like that are extremely anxious to see natural gas taxed, their point of view being that natural gas with a tax hooked onto it becomes uneconomic for industry, where the margins are very thin, and then that particular industry will have to use coal, because the natural gas company will not be able to sell its gas and there will be more work and higher pay for the miners.

It appears here that approximately 25 percent of the total gross revenues of those companies is derived from the sale of gas for industrial uses under what are called interruptible contracts. That situation adds to the hazardous position of these companies because of the thin margins which exist between the price received per thousand and what the gas costs delivered at the point of sale.

1110 Investors would take cognizance of the fact that the gas is being transported a distance of 950 miles, or more, by these pipelines before it reached the principal ultimate market. Investors are, generally speaking, slow to act and will act only in making investments in securities of companies which are to some extent seasoned, and a company such as this company, which has very long pipelines, the longest pipeline in the world, the largest diameter of pipe, the highest pressures used in the line, and being the only one of its kind and type, naturally does carry a greater risk than would the conventional type of natural gas pipeline with a shorter length and lower pressure. The reason being that, generally speaking, if anything goes wrong with this line it goes wrong in a big way. The pressures are very high, the fittings are expensive, the compressors are expensive, and our technology is not complete on the subject. By that I mean that there is no history in this type of line from which to gauge its future conduct as it ages.

If a distributing company has a line failure on some part of the line, it does not put the whole system out of business. Distributing companies are usually looped in so many places that a failure at one particular part of the line affects only a small portion of the distribution system. That is not true of pipelines. A failure of the main line at any point is an interruption of service, provided the gas in the line between the break and the point of sale is not sufficient to carry you over the time when you can get the line repaired.

From the standpoint of an investor, the circumstance that there are 31 different streams, including the Mississippi and the Missouri Rivers, and many other rivers of major magnitude, including the Canadian River, which in many cases are very flashy, between the initial compressor station on the south end of the main pipeline, and the City of Chicago, would enter into the evaluation or the appraisal of the securities of defendants.

Taking into account my knowledge of the facts concerning the extent and character of the investments of these pipelines, their location geographically, and with reference to streams and other considerations, the fact that they are a pipeline producing and transmission system with no control over their markets and with no distribution systems, and in the light of their special risks, and of the risks which they have in common with other pipeline companies, and with other business organizations, and in the light of the general background of information which I have concerning the evaluation and appraisal of securities and the requirements for raising capital money on the securities of business institutions, and in the light of all of the circumstances which in my judgment enter into a reasonable and proper appraisal of the various risks and hazards which have confronted these pipelines, and now confront them, I have an opinion as to what would be a proper and reasonable rate of return, or a fair rate of return for these companies.

In arriving at my opinion that not less than 8 percent is a proper rate of return for an enterprise such as defendants, after proper amortization, I am primarily guided by my own experience, knowledge and judgment of investments, and my experience in that field extending over a period of years. However, in order to check that judgment, I have prepared the exhibit which I formerly testified about, namely, Exhibit 150, containing a number of statistical tabulations. These tabulations are the sort of
1111 thing that anybody who was forming an opinion as to such a question would be bound to take into consideration. I was putting down in black and white what goes on in my mind in forming an opinion as to a proper rate of return. You have to give consideration, in forming such an opinion, to what yields exist on other natural

gas company bonds, to what other natural gas company stocks are doing, and you have to give consideration to a great many things. These exhibits simply put down in black and white what I considered points which were deserving of some emphasis as being among the things considered in forming this opinion.

The rate of return to which I have testified does not include any part of the amortization required. That minimum of 8 percent is based on the assumption that the proper provision for amortization or return of the capital investment will have been made. If the period of amortization be over the entire period of the indicated life of the field, an investor would want his 8 percent during the time his funds were used, but at the same time he would want to be assured that those funds were returned to him when the project was finished. If in fact 15 years is the life of this project, he would want to have his funds returned to him at the end of that period. If the project lasted only 12 years, it is obvious that he will lose a part of his investment.

From a practical point of view an investor would demand that the period of amortization under regulation be less than the life of the project as expected at the time he made his investment, in order to provide a factor of safety. If at a later time it is found that the project is going to last longer, the amortization could be changed at that time with no loss to anybody. If, however, the amortization is extended throughout the indicated period and not over a shorter period, there is a risk there. If the organization is set up under regulation on a 15 or 16-year basis, and actually works out to be only a 10 or a 12-year proposition, the investor will lose. Therefore, the investor before he goes into the thing will demand some compensation for that risk. I have included that element of risk in the 8 percent I named as the rate of return.

The Northern Natural Gas Company bonds to which I have referred were for a period of 12 years, and represented only 40 percent of the total capital value. The Equitable and the other companies fixed the maturity. We would not buy a bond with a maturity of more than 12 years. We had the engineers' reports which indicated a life of from 15 to 20 years, but we insisted on setting them up on a 12-year basis because we wanted to play safe. That was in 1935.

Cross-Examination by Mr. Booth.

I have not stated and certainly not at any one place all of the factors of the exhibit I produced here in arriving at my judgment as to what constitutes a proper rate of return for defendants. Rather than to undertake to answer your question as to whether or not I considered any other factors to which I attached any significance, I would rather mention right now the factors which I have taken into consideration in forming my opinion so as to have them in one place. I have not in any one place here
1112 enumerated the factors which I have taken into consideration, and I did not wish to reply to your question, "Are there any other factors that you have given consideration to," without thinking the thing through very carefully and giving careful consideration to all of the factors that I have considered, and I will be glad to name them right now.

In forming my opinion as to a proper rate of return for a company such as defendants, I gave consideration to such matters as the financial history of the company, the record of operations and earnings extending over a period of time from the time it became a going concern up to the end of 1938 and through the middle of 1939. I gave consideration to all of the facts which I determined in my investigation of the company from its records, and a physical inspection of the properties, such as its supply of gas in Texas, its sale of gas in Chicago under contracts. I gave consideration to the investors' appraisal of the natural gas industry, and I gave consideration to the present day financial conditions, the state of the money market. I took into consideration the returns which are available to investors in other businesses, the fact that these companies are now regulated or at least the rate case is in progress, and of course I took into consideration by general background and knowledge of the public utility business and the natural gas business extending over a substantial number of years. I may have left some factors out of that statement—it is not always possible to sit in the witness chair with questions thrown at you and detail a long list of things that you took into consideration. Certainly, I took all of those things into consideration, and there may have been some of the minor ones that I should have specified, but I think that they would fall into the general category of the conditions of the general money market and the demands of investors. I referred to risks of the natural gas business and to the possible failure of the line and the shortening of the life of the operations as one of these risks. I have said that I included among my considerations such matters as the risks inherent in the natural gas industry. I have given consideration to that circumstance as one of these risks. I spoke of the possibility of the shortening of life and possible over-estimate by geologists as to the life of the company. I also referred to rising costs as a possibility and the possibility of taxes on natural resources and the absence of control over the markets.

As to what I meant by the latter statement, any natural gas company which has control over its market through the ownership or control of the distribution facilities is, in my opinion, in a much stronger position from the point of view of the investor than a company which has no control over its markets.

In response to questions by counsel for defendants I pointed out the degree of risk attending companies like defendants and that it would be higher in a case of a company that was solely a natural gas production and transmission company than in one which had an integrated system, owning distribution facilities as well. I assumed, of course, that defendants have no control over the market because they own no distribution facilities. I am familiar with the situation under which defendants operate and I am saying that the conditions under which they operate tend to make it a more hazardous enterprise than if it controlled its distribution. I have attached a somewhat higher risk to the business of Natural Gas Pipeline Company because it does not own the distribution facilities in the City of Chicago and the adjoining cities in northern Illinois and does not control the market.

1113 I have not said that they have no control at all over their market. I know that defendants have contracts with Chicago District Pipeline Company.

In arriving at a proper rate of return for defendants, I have assumed the facts as I found them out.

I assumed that defendants had no control over the market as I have been using that term in my previous testimony, thinking of ownership of distribution facilities and in no other manner, and I attach a higher risk to the business and operations of defendants in arriving at my judgment as to what constituted a proper rate of return than I would have, had defendants owned the distribution facilities which were ultimately used in the supply of gas to the consumers. The bulk of defendants' gas is sold to Chicago District Pipeline Company as the first purchaser. The largest purchaser from the latter is Peoples Gas Light and Coke Company.

I have, among my papers here, the complete breakdown of taxes in Illinois and other states, paid by defendants. My memory is that the taxes paid to the State of Illinois are not large. In comparison to the size of the enterprise and its gross operating revenues, the ad valorem taxes paid in Illinois are relatively small—$40,000 in 1938, out of total taxes of about $629,000 paid by Natural Gas Pipeline Company for that year. The latter amount included ad valorem, federal income and other taxes.

Redirect Examination by Mr. Morgan.

I considered all of the risks that I discussed in my testimony in arriving at my opinion on rate of return. I certainly meant to include all of the factors which I had mentioned as I proceeded with my testimony from the very start, when I attempted within the limits of my memory to summarize them. I wanted to have this summary in one place and have it clear that when I enumerated the factors that I had taken into consideration, that I had not left out things that I really should not have left out.

Questions by the Examiner.

As to the weight I gave data shown on pages 6 and the following of Exhibit 150, in arriving at my conclusion, I certainly could not say what percentage I gave it. I think really all of that data in that section of the exhibit, as well as all of the exhibit, puts down in black and white, and under convenient headings, information which is available, and must be available to anybody in forming an opinion of this kind. The person considering the subject would roll this data around in his mind and give it the weight which he felt it deserved in arriving at a judgment figure. He would not have to know more about the industries which I have classified there before he could do that.

That particular list on those pages is a very, very large cross-section of American industry. I wish to make it clear that in reaching an opinion that 8 percent is a proper rate of return of this company, I am not influenced
1114 in any way by the fact that the steel industry or the automobile industry, say, earned 15 percent and consequently that there should be a tendency for a higher rate of return. I have not been influenced by any individual industrial classification, or the fact that profits were particularly large in particular industries or lower in other industries, but it was interesting, and I think of some value, to have before me a whole review of American industry showing what invested capital is earning over a period of years.

It is valuable for trend purposes, because you can see there, for the years 1934, 1935, 1936 and 1937 what happened in those years. 1937 was the year of business recovery and profits, generally speaking, were larger. As to whether I consider a 4-year period as here selected to be a good trend period, I do not think so. I could only select the 4-year period because these reports were data which were originally taken from the Securities and Exchange Commission reports, and that Act only became effective in the year 1934, so reports under the substantial breakdowns which are required for that particular kind of a tabulation only became available to the general public as of that year. From that point of view that is the best that we could get.

If I am to express an opinion as to whether principal or minor weight was given to the gas company studies shown in the same exhibit, a greater weight would, of course, be given to the statistics of the gas companies because those are the companies which are most nearly comparable to defendants. I do not mean to say that I did not give any particular weight to these other industrial classifications. If I had not, why should I bring the exhibit in?

I am familiar with the Federal Communications Commission publication of June 15, 1938, with special reference to the Long Lines Department of the American Telephone & Telegraph Company and with the observations made in that study. I think it is one of the best works on rate of return that has ever been produced. That is my bible, as far as that is concerned. I wish to make this observation, though: That that particular study was prepared by the Communications Commission with reference to establishing a proper rate of return for the Long Lines Department of the American Telephone & Telegraph Company. I think every one of us will admit that the Telephone Company has an absolute monopoly, to the extent that there is anything that is an absolute monopoly,—a real monopoly in communications service. To that extent it was perhaps proper that any comparison should not include any such things as industrial companies, but defendants are really primarily industrial companies who are in competition all the time with other fuels, such as oil and coal.

The Telephone study, except for one or two indices of that kind, did not go outside of the field of regulated enterprises. I feel, however, that it is desirable and necessary to go outside of that field in the case of defendants, because I feel that it is a different kind of an industry than industries which are primarily monopolies.

It is obvious that the rate of return for a single industry, contained in that list on pages 6 to 15 of Exhibit 150, is meaningless. In the case of the beverage industry, which shows an average return of 47 per cent, one company in that classification, namely the Coca Cola Company,
1115 makes a large return and overshadows the industry
as a whole. Similarly, you will find that in certain years other companies have made very low returns. All that the exhibit does is to show the rate of return for a very, very large cross-section. I think that some significance should be given to the average down at the bottom, and perhaps leaving out any individual industrial classifications.

The fact that this data on page 6 of my exhibit did not show what the investor is now getting by way of return on his investment, but merely a rate of return on the capital invested, which may have been invested years ago, does not affect the use of these figures, in my opinion. It is obvious from the heading on my exhibit and from the studies themselves that it is a return on invested capital, which may have been invested years ago. I would still use those figures for reference purposes because it is useful to know what capital is earning. It would be more useful to know what capital which is being invested today is earning or getting on its investment, if it were possible to obtain such data in as comprehensive a way as that information is set out in the exhibit. That would certainly be another measure. I would say it would have at least equal and perhaps greater value.

(At this point EXHIBIT 150 was received in evidence over the objection of counsel for each of the Commissions, to whom the Examiner allowed exceptions.)

Redirect Examination by Mr. Morgan Resumed.

In stating, in reply to questions by Mr. Booth, that in appraising the risks attendant upon the investment in these companies, I asumed that they have no control over their market. I understood that they have contracts with the distributing companies who market the gas to the ultimate users. I so stated at the time and in saying that I assumed they had no control, I meant they had no such control as was not given them through operations of their contracts, of course: I was differentiating between the control which comes through ownership of distribution facilities as distinct from these companies which have contracts for the sale of their products. I was talking about the retail marketing policies of the distributing companies and all of the other things that are within the control of the companies which sell to the ultimate consumer at retail.

Recross Examination by Mr. Booth.

I have said that in arriving at my judgment as to the rate of return, I regarded that these companies are a riskier enterprise than would be the case if they owned the distribution system; and, in arriving at my judgment, I assumed that they had no control over the market, except such as they acquired through the contracts for the sale of their gas. These contracts do not give control over the markets in the sense that I was using the word "control". As I was using the term, I mean the company which owns the distribution facilities and sells the gas at retail to the public, and in that sense controls his market. I did not say this morning that I considered the fact that defendants had this contract with Chicago District Pipeline Company was of no significance. I gave consideration to the terms of the contracts under which gas is sold, the length of the contracts and the prices at which it is sold. These, I think, are the principal factors concerning those contracts. I have not said those particular factors increased the risk of defendants. If a company had no contract whatever, and was simply selling its gas on a day-to-day basis, the prop-

1116 osition would be much riskier than that of defendants. They are in a much better position than a company that would have a day-to-day or a month-to-month contract. And I considered that on the whole the relations between defendants and Chicago District Pipeline Company had the effect of increasing the risk over that of a company that owned its distribution facilities.

The fact that these contracts were for 15 years from the date they were written, with a privilege of extending for 5 years on the part of defendants, reduces the risk from that of a company which operates on a day-to-day basis. I know of no natural gas pipeline company that operates on a day-to-day basis. In arriving at my consideration of the risk, I took into consideration all of the terms of the contracts which I read. I should hate to state from memory the terms of all the contracts. I have stated what I consider to be the principal features, the life of the contract and the rate at which the gas is sold. There are many other provisions in those contracts with reference to the adjustment of the contracts, taking care of the impurities of gas, and all sorts of things. The principal factors which I took into consideration in those contracts as affecting the risk were the terms and the price at which the gas was sold.

I testified that 8 percent was the minimum rate of return for defendants. This I consider a proper or reasonable rate of return for defendants.

1117 **H. B. DORAU**, a witness for defendants, testified:

Direct Examination by Mr. Morgan.

(October 4, 1939)

My name is H. B. Dorau. I reside at Ridgewood, New Jersey. I am professor of economics at New York University and chairman of the Department of Public Utilities and Transportation in the School of Commerce of that university. I lecture in courses in public utility economics and courses in property valuation. I also conduct graduate seminars in public utility problems and in economic theory in the Graduate School of Business Administration. I came to New York University in 1931 and have been teaching public utility courses in that university from that time down to the present.

Prior to that time I had been professor of economics in Northwestern University, teaching courses in public utilities and directing the research projects in public utilities conducted by the Institute for Economic Research at Northwestern University School of Commerce. I was on the faculty of the School of Commerce of that university from 1925 to 1929 in which year I was granted a leave of absence to engage in economic consulting work for investment banking firms. My leave of absence was extended for a second year to 1931.

During that two-year leave of absence from teaching and research I had a variety of experience as consulting economist in connection with investment and financing proposals.

Prior to my tenure at Northwestern University I taught as a member of the Department of Economics at the University of Wisconsin from 1921 to 1925. That was my first teaching appointment.

I graduated from Lawrence College, Appleton, Wisconsin, in 1919 with an A. B. degree. I did my graduate work at the University of Wisconsin from 1919 to 1923 and was awarded degrees of Master of Arts and Doctor of Philosophy by the University of Wisconsin.

I have always engaged in business and government consulting work to the extent that my university appointments permitted. My first employment came in 1920 when I was retained by the public utility acquisition committee of the Common Council of the City of Milwaukee. My special responsibility was to determine the probable cost of capital to the City of Milwaukee should it acquire the electric business, and compare that probable cost with the experienced cost of capital to the private company serving the city. That was a study to determine the annual value of capital in the employment of the public utility business under two forms of ownership. I would say it was in the nature of a rate of return study.

1118 I have made a number of investigations of the cost of capital to regulated enterprise. I made an early study of the cost of capital for public service enterprise which was published in the Chicago Journal of Commerce in 1923. I initiated studies on the cost of public utility financing in 1925 which were published in the Journal of Land and Public Utility Economics and which studies have been kept up to date by myself and others since that time. I have published comprehensive articles on the changing cost of public utility capital. I made up a detailed study on the cost of capital experienced by the railway industry under the operation of the Transportation Act of 1920 which study was presented to the American Economic Association in St. Louis in 1927 and subsequently brought up to date and published in various banking and economic journals.

I have appeared as a witness in the field of public utilities before regulatory bodies on a few occasions. I have appeared before the Interstate Commerce Commisison, before the Illinois Commerce Commission, before the Pennsylvania Public Service Commission, and have acted as consultant from time to time for the Board of Public Utility Commissioners of the State of New Jersey. I have been responsible for the presentation of economic briefs and analyses in connection with a consirable number of public utility cases on which I did not appear as a witness.

I have written textbooks and other published articles in the field of economics and public utilities. I have here a list of those publications and books which I do not pretend is comprehensive or all-inclusive, because my memory fails me on a great many of these things. I have never had time to keep a scrap book and record everything that I have done. The list includes:

Dorau, H. B. "Public Utility Financing, 1919-1925," Journal of Land and Public Utility Economics, July, 1925.

"Public Utility Financing, A Review of 1925," Journal of Land and Public Utility Economics, April, 1926.

"The Cost of Railway Capital under the Transportation Act of 1920," American Economic Review, March, 1927. Journal of Land and Public Utility Economics, February, 1927.

"Northwestern University Responds to the Demands of an Important Business," American Gas Association Monthly, March, 1927.

"The Rise and Decline of Municipal Ownership in the Electric Light and Power Industry of Wisconsin," Journal of Land and Public Utility Economics, May, 1927.

"Municipal Ownership in the Electric Light and Power Industry of Massachusetts," Journal of Land and Public Utility Economics, August, 1927.

1119 And Alexander Marjorie. "Some Measures and Measurements of Telephone Utility Taxation," Journal of Land and Public Utility Economics, November, 1927.

"Gross and Net Earnings of Public Utility Enterprises Exclusive of Steam Railway, Telephone and Telegraph Utilities, 1913-1926," Journal of Land and Public Utility Economics, February, 1928.

"Appliance Merchandising Policies and the Future of Gas—Should the Gas Company Set the Standard for Appliance Selling in the Territory Served with Its Products?" Gas Age-Record, March 3, 10 and 17, 1928.

"Merchandising as a Factor in the Gas Industry," Gas Age-Record, June 16 and 23, 1928.

"Cost of Railway Capital," Journal of Land and Public Utility Economics, May and November, 1928.

"The New Competition—How to Meet It," American Gas Association Monthly, December, 1928.

"Cost of Railway Capital," Journal of Land and Public Utility Economics, May, 1929.

"Railroads' Command of Capital," Investment Banking, August, 1931.

"Some Alternative Bases for Public Power Projects," The Southern Economic Journal, April, 1938.

"Dispersion of Prices for Domestic Electric Service," Public Utilities Fortnightly, June 9, 1938.

"Rates in the Electric Industry Under Municipal Ownership," Annals of the American Academy of Political and Social Science, January, 1939.

"The Impact of Economics on Accounting," Edison Electric Institute Bulletin, January, 1939.

"The Outlook for Public Utilities," Trusts and Estates, January and February, 1939.

Bailey and Knowles. "Public Utility Accounting Procedure." A. W. Shaw Company. Chicago. 1928.

That list shows the books or publications of which I was the sole author and also those of which I was co-author or joint author. My responsibility in connection with each is clearly stated in the list.

In some instances I edited these publications and was not the original author. Editing a publication involves a wide range of responsibility,—sometimes a very considerable responsibility in the selection, rejection and arrangement of material and sometimes less responsibility. I merely mention two here because they are rather closely related to the field with which we are concerned, namely, Lagerquist on Public Utility Finance, which I subsequently edited for publication, and Public Utility Accounting Procedure by Bailey and Knowles, which I took a hand at arranging or improving for publication.

1121 I have been asked to make an investigation of the factors influencing the necessary rate of return to which defendants in this proceeding are entitled. To the best of my recollection I was employed in the beginning of April, 1939. I have not kept a clock record of the time devoted to the gathering of information and the development of my conclusions in this matter. That is impossible with the conditions under which I work, but I have devoted a very substantial part of my time since that date to special consideration of the question of the necessary rate of return for an enterprise of this character. I have had the assistance and advice of my associates in the Department of Public Utilities of New York University and others trained and qualified by experience to participate in statistical and economic investigations of this character. I have had the aid of qualified economists, statisticians, lawyers and engineers in the work of assembling information and determining quantitatively and statistically the facts upon which I base my opinion. I have directed the work of all those who have contributed to that study and their work has been done under my immediate supervision. I have kept up with it as to progress.

The word "return" to my mind refers to that part of the revenue of an enterprise remaining after the deduction of necessary operating expenses including rents, taxes and provision for accruing depreciation, but before provision for interest, dividends or other appropriations which in one form or another constitute compensation for the employment of capital. The return may thus be designated as the "wages" of capital, or more appropriately the return available for all the providers of capital for the various economic functions which they have performed.

There is no provision in the "return" as I am using that term here for the return of the capital through depreciation or amortization or some such provision. I consider provision for depreciation as an appropriate operating expense which has to be deducted from the revenue before you arrive at the wages of capital.

There is a distinction between return on capital and the return of capital in an economic sense. The capitalist requires an annual wage on the capital and looks forward to the ultimate return of his capital. Therefore I would say that the provision for depreciation represents the anticipation of the return of capital, and therefore should not be included in the calculation of the return on capital. Capitalists are simply of that variety who expect a return of their capital as well as a return on their capital.

Here I am speaking of the return on capital only being determinable after adequate provision for accruing depreciation. The wages of capital to which I referred a while ago are received by the enterprise which engages in the business to which attention is being directed. What I mean to imply is that strictly speaking the security holders won't receive the return. The security
1122 holders receive their respective shares out of the
sum which constitutes the return on the capital of the enterprise in whose securities they may have invested. They receive a return according to the particular contract on which they may have invested or engaged their capital. I also mean to imply that it is my opinion that security holders as a whole viewed separately rarely receive the whole return which the enterprise may receive. There are generally charges and adjustments to be made which cannot be made in any other way except subsequently against the amount which was earlier thought of as part of the return. Consequently, I would distinguish between the security holder's return and the return receivable by the enterprise as such, because as a matter of historical fact, the security holders rarely receive the whole return allowed to the enterprise.

What I meant to call attention to was that the amount calculated or anticipated as the return to the enterprise is rarely the amount which the security holders as a whole receive in compensation for the performance of their economic functions.

From the standpoint of an economic analyst it makes no difference as to the rate of return to which an enterprise is entitled whether its securities be in the form of bonds or preferred stock or common stock, or ordinary interest-bearing indebtedness like that to banks. The fact that some capital is compensated on a contractual basis in the form of bond interest, and other capital is compensated by an agreement among stockholders that some shall be preferred over the other classes of stockholders, does not make any difference. I do not conceive the problem of the return determination to be confused by the nature of the capital bargain made among the various classes of security owners. That is a bargain which they make with each other among the groups represented. There is a difference between the earned return and a return to be earned. The return earned is of course a historical fact subject to determination within the limits of accuracy of accounting and statistical devices. It is something that has occurred and is in distinct contrast with and a very different sort of thing than the return to be earned, which is the question arising in connection with a rate case. Thus, one is an established past fact; the other is a presumption or an opinion, a judgment or anticipation, and since the past and future are very different, and since estimates and expectations and past established facts are different, they are two very different quantities and two entirely different concepts, in fact.

The return is ordinarily understood to be the product of the rate base multiplied by the fair rate of return. Thus, while the return is a number of dollars and is the ultimately important fact to be determined, it is only ascertainable by applying a previously determined rate of return against a previously determined rate base.

The return is ordinarily expressed as the rate of return applicable to an annual period because the year is
the unit of accounting and financial record keeping,
1123 and therefore it is convenient to express it as a
return in a year. A return of 8% then means 8% of the rate base each year. By the expression "fair return" or "reasonable return" I would say that it means the income on the value of the capital employed which in the best opinion and judgment is necessary to fully compensate the capital employed for all the necessary economic functions performed by its investment in a given enterprise under a given set of circumstances. The use of the word "fair" is meant to imply the dependence on judgment and opinion since it is a future fact which is being estimated.

A fair return in my opinion cannot be ascertained with the same degree of precision as can a past return because the latter is an experience and the former is an expected fact. Since the one involves judgment and imputation for the future it can never be hoped that it will be precise to the same degree that an experienced fact is. The necessary return as distinguished from the rate of return is never directly determinable. The return is the product of the multiplication of the base value by the rate of return. Neither rate base nor rate of return is an ultimate end but on the contrary they are but the indispensable means to the important end, namely, the return stated as the number of dollars.

I am not prepared to offer any opinion on the rate base. In my study concerning the rate of return I assumed that the rate base is going to be determined and since the rate base is not as yet determined I cannot determine the return as such. All I can concern myself with is the rate of return which will have to be applied to some rate base out of which the ultimate fact which interests all parties, namely, the return, the number of dollars, will have to be derived.

I have made a study of the records and the facts concerning these two companies and the character of business in which they are engaged in an attempt to prepare myself to the best of my ability concerning this subject of a rate of return here.

I have devoted my study and am prepared to testify here concerning that subject only. It is essential in order to obtain a fair return for an enterprise to have both a fair rate base and a fair rate of return. The presumption is that if the return, namely, the number of dollars, which is the vitally important thing, is to be fair or to be arrived at at a figure which would be deemed to be fair, then the two calculations which are necessarily previous to that determination would presumably also have to be fair.

In approaching the subject I tried to make the distinction between ascertaining the return actually earned in some past period, and ascertaining the return deemed fair or necessary for some future period. I should like to make the distinction again between ascertaining a past return and a present or future return to the effect that one
1124 is the ascertainment of a fact. I say that because I
want to make it perfectly clear that determining the necessary return for the future involves the process of valuation. It is unavoidably an imputation process, since even identical past transactions do not establish what the necessary return shall be for the future. It is an imputation process even more remote than that which is engaged in when the owner of a thousand bushels of wheat imputes a value to it based on yesterday's price at which some other wheat was sold. The process of determining a fair rate of return is the same as determining the fair value for rate

base purposes. It involves the gathering and selecting of evidences and the passing of judgment as to the significance and weight to be attached to each form of evidence.

In my opinion the appropriate evidence of the necessary return is the present annual value of capital under the conditions under which it would now be employed. It is assumed that the return to be determined is the presently necessary return. This in my opinion is the common understanding and apparently the law of the land. The question is not how much of a return was necessary five years ago or how much of a return may be necessary five or ten years hence, but what are the necessary present annual wages of capital under the circumstances of employment were the enterprise to be undertaken today. The use of present annual value of capital is entirely in harmony with the use of the present capital value for rate base purposes. Thus, the sum to be determined is the present necessary supply price of capital under the conditions which enterprising capital would face were it considering committing itself to this kind of employment today. I mean to say that the fact to be determined is at what prospective return would capital employ itself if a given enterprise were initiated under present day conditions. It is my understanding that experienced money cost refers to the price at which a given enterprise actually was able some time in the past to secure the capital which it now commands. I understand present necessary supply price of capital to mean the price at which such an enterprise could now expect to command the capital necessary to establish itself under present conditions.

In my opinion the experienced past cost of capital of a given enterprise has nothing in particular to do with the present annual cost of capital employed. The experienced money cost of an undertaking may have been higher or lower than the present annual value of the capital employed under present conditions. If the experienced money cost is recent and the conditions of capital employment have not significantly changed, experienced money cost may be significant evidence of what the present annual value of capital under given conditions of employment would probably be. Since all valuation consists of imputing a money-worth to goods which actually are not being exchanged, it is necessary to seek and appraise the evidences of value in the absence of such adequate market demonstration. The evidences of value, in my opinion, with respect to rate of return and with respect to other valuations, do not have equal significance at all times. Apparent evidences may have no real significance at some other 1125 times. Thus, it is possible that the past experienced cost of capital does not reflect even as of that date the annual value of the capital employed. In the case of the Natural Gas Pipeline Company of America it appears that there was no public bargaining for the capital, that the yield on the bonds at the offering price was nominal, since equity ownership and residual claimant interests purchased these bonds. In such absence of any bona fide market transactions for this capital the nominal apparent experienced money cost, in my opinion, loses all significance.

The experienced money cost and the required return are not at all necessary on the same level. The lapse of time between one bargaining and another would very likely introduce changes which would make the present annual value different from the experienced cost of capital even if the experienced cost were a bona fide reflection of arm's length bargaining for capital.

(October 5, 1939)

They are not only not necessarily on the same level but they are rarely on the same level, because we are living in a dynamic economic society in which those relationships are continually changing.

To the fact that a company had succeeded in issuing bonds that would yield to the investor 6 per cent back in 1931 or 1932 I would attach no particular significance. In the first place that is seven or eight years ago. There have been significant changes in economic relationships during that period. Furthermore, I would want to know under what conditions and circumstances those bonds were issued at that time, particularly whether or not they even reflected with any degree of accuracy the market's valuation of that kind of a return at that particular time, and quite obviously whether it was an arm's length bargain. In other words I would want to know that it actually reflected, even as of eight years ago, the capital market conditions for such capital as may have been acquired under the conditions then existing; that it even had the essentials of an index of the value of money as of that time.

I think it is important to recognize that the present necessary supply price of capital is not a single homogeneous form of economic compensation. From the accountant's point of view and from accounting records it would of course appear to be such, because it is regarded as a num-

ber of dollars of income, or viewed as a number of dollars of income to be obtained; but when you approach the problem of an economic valuation of such a return it is necessary to recognize that it is made up of a number of non-homogeneous elements, each of which is subject to influences peculiar to itself. That these various elements cannot be too accurately identified or segregated from the whole is in my opinion no excuse for failure to recognize that they exist. I think this is particularly important when dealing with a peculiar industry and it is also important when dealing with an industry having peculiar and unusual circumstances, because not only are you faced with the problem of recognizing the fact that there are in the so-called return a number of non-homogeneous forms of reward, but that the relative importance of these various
1126 elements changes from time to time, and that under one set of economic conditions one of the elements may be much more important both relatively and absolutely than it would be at another time. These components can be broken up in a number of ways. For the purposes of my own thinking I like to break them up into two parts initially, one of which we may define or consider as loan interest and the other as that amount over and above loan interest which constitutes the necessary inducement to enterprise in the form of rewards over and above what loan interest would be in such an undertaking.

As every one probably knows, loan interest itself is far from a homogeneous form of compensation. Any effort at more accurate and refined appraisal would envision the elements that go to make up loan interest. Thus we recognize in economics the primary element of pure interest. We recognize also that there is in loan interest a risk premium. It ought to be recognized that there are over and above risk premiums certain compensations for uncertainties which are really not of the nature of risks. There is I believe in a great many interest loan contracts a fourth element, namely, a necessary compensation for the performance of the work of watchful care and attention to the investment.

Pure interest is of course an economic conception of a portion of the loan interest. I consider it the most fundamental but it is by no means quantitatively the most significant. What is important in the first instance to understand is that this pure interest is not synonymous with and never measures the loan interest rate. In economic science pure interest is understood to be the market value of time preference. It measures the difference between the present value of the future gratifications and the present value of present gratifications. Thus pure interest, assuming the freedom of capital to move and assuming the absence of other restricting factors, would tend to be the same at a given time and place with respect to a given people, irrespective of the field of employment.

Therefore, it is not a difference in pure interest which would call for a decision as to the comparative relative rates of return to be allowed in different kinds of undertakings. The movements of pure interest rate are difficult to trace and never express themselves in the form of a market price. When the loan rate of interest, for example, changes it is not necessarily any evidence that the pure interest element has changed because the loan interest rate may be changing on account of the change in other factors. In fact we have reason to believe that the pure interest element does not change violently from time to time, that the people's disposition to prefer present over future gratifications does not fluctuate widely as the yields on contracts at loan interest fluctuate, for example.

In my opinion there are no loan contracts of any character whatsoever which accurately reflect pure interest. Moreover, I believe it is an error to assume that the yield on government bonds reflects pure interest. Government bonds play an important part in our monetary system.
1127 They serve several special and unique functions as
investments for the funds of commercial banks and moreover they enjoy a peculiar market because of the confidence that the people have in the government and the efforts which the government makes or has made in recent times to maintain a market in these bonds.

Moreover, to say that the yield on government bonds reflects pure interest puts us in a dilemma because we find government bonds yielding different rates of interest from a fraction of one per cent for short term obligations to in excess of two and approaching three per cent on other obligations. So if one were to say that the yield on government bonds reflects pure interest one would be put in the position of saying that there are many different rates of pure interest. The fact is that people buy government bonds, in my opinion, at prices which frequently sacrifice a portion of pure interest in order to obtain something which they consider of more value than the pure interest at the particular moment, namely, liquidity, the putting of one's self in the position to quickly withdraw from a given security and to be able to buy at another opportunity when the attractive time comes around. Government securities have, in my opinion, yielded less than pure interest under many circumstances.

There are many illustrations of the same kind of behavior. When people purchase common stocks where there is no present return and possibly no early expectation of return they are sacrificing an immediate return and balancing that off against future expected compensation. Because of accounting conventions we get in the habit of using the year for such calculations and for many investments the year is a perfectly arbitrary measure for such calculations. People usually envision a period of time and expect that in that period of time they will get a full and adequate compensation.

Take another illustration. A man who buys a vacant piece of land and is shown not to receive any return or any rent for a period of five years. I think it would be entirely inappropriate to use that as an illustration that people are willing to invest in land at no return. A piece of land that is expected to appreciate affords another illustration. It is common knowledge that when buyers and sellers get together on the price of a piece of land which it is understood is likely to appreciate, the ratio of available income to the price paid is very low, because the investor in that kind of an opportunity envisions the annual return plus the incremental or changing return will compensate him fully.

Years ago some interesting studies were made of farm mortgage rates and farm earning rates in the State of Iowa. It was surprising to find that the farmers were apparently paying a mortgage interest rate in excess of their current earnings rate. The paradox, however, was resolved by an understanding of the fact that they had gone through a period of rapid appreciation of land values and that they were envisioning a total gain in the value of the estates plus the current return which would be fully compensatory. The point is that the total return expected is not necessarily embraced in the current rate of return.

1128 *Cross-Examination Interposed by Mr. Slaff.*

"Pure interest" is not the return on a riskless loan as that term is viewed in economics. The effort is made to identify it with the differential existing in human being's valuations of the future and present gratifications. Insofar as they have notions of risk that enter into that calculation they would probably act differently than this pure conception of a distinction between present and future gratifications. For the purposes of the analysis which I propose to make, and in the usual method of thinking, we conceive pure interest as not including any compensation for the assumption of the risk.

As to whether I define "pure interest" as return on a "riskless loan" as you say Mr. Delafield did, I think I have answered you when I said that the conception of pure interest is the reward and compensation for pure time preference and not for any other element or any other function or the assumption of any other economic burdens. Thus by implication, my earlier answer seems to point to the fact that risk and uncertainty and the other elements are to be recognized as independent of this factor.

Direct Examination by Mr. Morgan Resumed.

There is no such thing as a riskless loan; consequently I am unable to compare those two things. Pure interest would more nearly approach the yield on as near to a riskless loan as one might be able to envision. I am perfectly aware that it is common practice to make reference to what are considered the most secure types of loan contracts as a reflection, but in a more refined analysis I merely want to point out that that is not strictly accurate and true.

The fact is that people are willing to sacrifice their entire valuation of time preference under some circumstances in favor of liquidity or in favor of security. Thus, the people who have maintained their purchasing power intact, in spite of inducements of any sort during the period of depression, were sacrificing the total of their valuation of the time preference in favor of the other things that they could only get by making that sacrifice. That does not mean that these people are bereft of any time preference. It simply means that they are willing to sacrifice and take the greater gain or choose the lesser loss under the circumstances they face. In other words, pure interest in its relation to the interest on a riskless loan would approach the latter when there are no other considerations than interest involved in the investment.

The observation I made with reference to government bond yields during periods of low economic activity to an extent applies to all high grade bonds. It is a practical observation drawn from the financial markets that those bonds which most nearly approach in security the position of government bonds are rather quickly influenced by the changes in government bonds. Exceptionally well-secured loan contracts of every character, maybe bonds, and the highly protected private securities, all represent what one might call a sort of bomb cellar to which capital retreats in periods of economic distress.

1129 As I pointed out, it is common knowledge that a great deal of capital prefers to remain totally liquid in times like these, receiving no loan interest at all rather than commit itself to any fixed obligation. There even have been periods in history when the indicated market interest rate appears to have dropped to zero and it is reported in earlier economic history that at times people even have paid interest for the safekeeping of funds under conditions of great hazard or great uncertainty. Thus, the phenomena of what we refer to as negative interest.

It is not reasonable, in my opinion, to assume that just because people choose the greater loss or the lesser gain at such times that they lose their sense of time preference. I think that such extreme illustrations merely illustrate the fact that pure interest return will be sacrificed at times in favor of other elements for the return. Thus the yield on high grade bonds tends to a considerable extent to be inverse to the necessary reward for the assumption of risks and uncertainty and the assumption of entrepreneurial responsibility,—lowest at the time when there is the least disposition to be enterprising and rising promptly when the possibility of gain commensurate with risk, uncertainty and enterprise appears. This in rather recent weeks has again been rather dramatically emphasized by the quick flight of capital from these economic retreats or bomb cellars to liquidity in the hope that the war situation would bring on an opportunity for enterprising capital to earn that kind of a return.

"Enterprising capital" is a general term which I use to imply capital which is interested, willing and able to assume some of the risks, hazards, uncertainties and even an entrepeneur position in industry. You would distinguish that kind of capital from the kind that insurance companies have, for example, which they are restricted in that instance by law from employing in that way. You would distinguish it from the type available with savings banks, the type administered by trustees. You would distinguish it from the estate of those who are wholly and totally dependent upon certainty of return for what funds they may have to protect them in old age or otherwise. It is the capital which is in a position to be utilized, either legally or economically, by virtue of the amount of money which the individual has or the position that he finds himself in with respect to the assumption of risks and uncertainties which would justify him in not merely employing his capital to equate time preference, but to assume some risks and hazards even to the employment for the support of the entrepreneur in a business engagement.

It is a matter of common knowledge that different types of loan interest contracts require a varying amount of the investor's attention and consideration. Obviously in the face of this fact the investor would avoid that type of commitment which would require his continuing attention and concern unless that type of commitment promises to yield somewhat more than a commitment which did not require that amount of attention. I think a good illustration is again found in the old-fashioned real estate mortgage investment which requires a great deal of capital management. It was usually necessary to give attention to
1130 investigating the property and the security. Following that it was commonly necessary to write once or twice about collecting the interest. Then you had to see to it that the insurance was kept up on the property and that the taxes were paid, and when you got all through and received your 6 or 6½ per cent return on the farm mortgage, which was probably very well secured, you undoubtedly had earned a fairly decent wage for the management of your capital, all of which was pretty effectively disguised as part of the loan interest rate. If you need any more evidence that there is an appropriate valuation to be attached to that kind of a function, we need only observe that there are commercial agencies, banks, trust companies and others who assume to perform the function of capital management and charge you a right handsome fee for it.

The cost of capital management is the amount received by the holder of the contract and is the amount paid by a business enterprise. I am not talking about any function performed by the agents of a corporation or business in whatever they may do to manage the assets of that enterprise. I was talking about the amount of care and attention which the owner of the securities had to give to certain types of securities as compared with other types about which he might feel very much freer and certain as to the future,—the contrast between the type that he has to give thought to, the kind that worries him a bit before he goes to sleep at night, as distinguished from the kind that he feels he can put at the bottom of a safety deposit box and forget about it until he wishes to dispose of them or until his estate has to liquidate them.

Well established industries and well established concerns in well established industries could offer loan contracts which would appeal to the investor, having a smaller necessary element of compensation for this exercise of the function of capital management. In contrast, a pioneering establishment which had not yet existed long enough to establish any kind of a presumption in the investor's mind as to what the kind and character of the investment really is would undoubtedly give him a very considerable concern. The point of the discussion is that the wages of capital management constitute an important element in the loan interest rate, and that this element is of varying significance in different industries and in different enterprises in different industries, as well as varying from time to time with general economic conditions. Consequently it is my opinion that this element is worth considering because it appeals to me as being peculiarly significant in the first place in the natural gas industry, and in the second place in this kind of an enterprise in the natural gas industry.

I am not talking about the expenses of operating a gas pipeline or gas production or any other activities of the gas companies. I am talking about the compensation that the person who is asked to invest in the securities of an institution of this kind will require for putting his money into this sort of thing. We are trying to refine an element which is often rather crudely dealt with into its component parts and it is important to do so whenever there is any peculiar significance to be attached to this particular element. It is my opinion that the natural gas industry
1131 is one where that sort of consideration is entirely
worth mentioning and giving some weight to.

Question by the Examiner.

To some extent it makes a difference as to how the investment is made, whether by lots of small investors or by a few large ones. For example, certain types of investments which would require a great deal of care and attention can better be handled in large blocks than in small groups. If an investor of $1,000 were to invest in a situation where a great deal of this attention had to be given, the labor of attention would probably overwhelm the total of the possible return that he would get. That was often my contention with respect to the real estate mortgage investment—that the amount of labor and attention required on the part of these people absorbed almost the whole return and that they were really kidding themselves into thinking that they were getting something comparable to or better than alternative investments available in the way of marketable bonds, for example.

Direct Examination by Mr. Morgan Resumed.

Any kind of an investment which requires additional attention, labor and concern on the part of the investor would require a higher return than one which did not. I hope I made perfectly clear that I am not trying to say that the money spent by a business in the development of its market and opportunities, or the money spent by the business in its experimental work, is involved here. I am not trying to count double. It is entirely unreasonable, I believe, to understand that the expenditures of the business enterprise are involved here.

What we have in mind is simply the time and attention, the energy, care and concern which the people who put up the money give to it over and above the attention which is given by hired managers, technicians, specialists, which the enterprise itself may hire. The very fact, I think, that an entrepreneur capitalist chooses to go into this kind of an undertaking suggests that he sees the possibility of selling what he has to sell in the way of capacity to give consideration and concern to the investment.

Furthermore, I think it is entirely contrary to the fact to assume that these enterprising capitalists can and do sublet all these functions of giving care and concern to the investment. As a practical matter, if they have confidence in their own opinion and are of that class, they probably cannot find the people in whose decisions they have equal confidence to their own and, secondly, if they went out to hire the performance of all of these functions they probably would have to pay substantially what it is worth and there would be no margin in it for them. If the people who have this capital were not disposed to look for a return to compensate them for the performance of that function, they would in all probability be buying relatively risk-free bonds and becoming passive capitalists rather than enterprising and active capitalists.

1132 I make the distinction between cost, as I have used that term here, and expense that is commonly made in economic analysis. Not all costs reflect themselves in the form of expenses. I conceive an expense as a cost which has reflected itself on an accounting statement or as a fact in a business record by virtue of one party paying another for something. But there are a great many instances under which costs do not reflect themselves in the form of expense and that is, of course, what I had in mind in the distinctions that I have been trying to make here with respect to the wages of capital management. The payment for an expert employed by the enterprise itself becomes an expense of that business and is accounted for and recorded on the books of account. But the performance of the function of capital management does not take the form of a transaction. It is something that the individual does directly for himself and consequently accounting as a system of business record keeping has not developed any devices by which in a practical way we can record and reflect costs which do not express themselves in the form of expenses.

In simpler forms of business undertaking that of course is well understood. The farmer who employs a hired man has an expense for the hired man but the labor which he himself performs is just as much a part of the cost of producing his potato crop as the expenses that he incurs on account of the hired man; and it is just as worthy of recognition in an analysis as if he had made the expenditure. Consequently, the function performed by the capitalist, in my judgment, for himself in engaging in capital management is a cost which should be recognized even though it does not take the convenient and obvious form of an expense in the accounting records.

Question by the Examiner.

In my opinion there is no complete difference in the concept of the wage of capital management, whether the management process takes place after the investment is made or as a preliminary thereto. The performance of the functions of capital management to a considerable extent precede the actual commitment of capital. In fact, much of the work is done normally prior to an actual commitment. It continues while the capital is committed, in fact, continues until the time that the investment is liquidated. As a result it is a continuous function, starting from the time the individual incurs these costs in the exercise of care, attention, concern and the application of intelligence which are not reduced normally and readily to an expense record.

Direct Examination by Mr. Morgan Resumed.

To apply the principle of the illustration, the man who makes the loan on the farm will inspect the land, have the title examined, draw the note and mortgage, file the mortgage, pay the fee and do a lot of things before he lets the money get out of his hands; but he knows at that time, if he is an experienced investor in farm mortgages, about those things that he is going to have to do hereafter in order to get the interest and see that the things are done which must be done for his protection,—that the insurance is not only placed on the improvements but kept on them during the continuance of the loan. That kind of transaction happens to be in a field in which I have some personal experience and it comes readily to mind as one
1133 which illustrates the performance of an indispensable
economic function which demands that it be compensated but which is often overlooked simply because it does not take an obvious identified form in market transactions; and it was my opinion that since it did not take the form which would be readily reflected as an expense that the appropriate way to recognize its cost, its compensation, is in the return and that is in fact the way in which it is normally compensated and, I believe, the only appropriate way to compensate it.

Questions by the Examiner.

You ask whether the labor incident to changing an investment could not be charged off against the existing investment rather than charged off against the future. I believe it is in the nature of human investment psychology to look forward much more than to look backward. While the money is being held and the owner is looking for an investment the cost incident to the interval might be termed negative interest. As it was suggested to me in connection with some investment banking investments in 1929 and 1930 and even in 1931, "Why not take a look at the possibilities in the natural gas business?". The question was put to me as a consultant and this particular organization had not had any experience in that particular line, had not been in it before, and my advice was that the cost of just getting constituted and acquainted and going through all that for that concern made it rather impractical even as an opportunity in that day when opportunities were getting scarcer and scarcer. Because we look forward I think it is dominantly in anticipation, and I think appropriately it begins when you have a reasonable thought of considering seriously a given opportunity.

Direct Examination by Mr. Morgan Resumed.

I am talking about the cost even prior to the planning, designing, weighing and balancing of the terms, and the difficulties that enter into the matter from the time a particular enterprise is conceived of. I think that just as soon as the investor has a reasonably substantial interest in considering the possibilities of a given line of employment of his capital he will then be conscious of the amount of extra attention, concern and effort that this particular line would impose upon him in the light of the return which is probably available; and he would make a comparison between that and the alternatives that would be available to him which in his mind probably would not require the same amount of attention. If he is thoroughly discouraged about the amount of attention or consideration that he would have to give the employment of capital under those conditions he will probably have recourse to a passive investment in the form of well-established bonds.

In other words, my thought is that if one who incurs these costs of whatever character they may happen to be which are not included in the operating expenses after the enterprise is put into operation, but costs which are outside of that such as the cost of mapping out, planning, etc., and putting the enterprise on a going basis into which the money is to be invested, and the cost of keeping up with that investment after it is made, is denied compensa-
1134 tion for that, men will cease to be enterprising and will put their money in passive investments. If we

are to have capital for enterprises of this sort we must compensate those who perform those services. It is by no means a theory but an actual fact that investors do distinguish among investments on the basis of the time that they have got to give to them. In certain sections of the country there is a lot of old accumulated capital, third and fourth generation capital, traditionally alleged to be the case at least with respect to New England. For a great many years you were asked, "Well, have you got distribution in New England? Have you got dealers in New England?" "Yes." "Well, you cannot sell this kind of security in New England, because they just want the kind that you can put down in the bottom of the strong box and forget about it."

An example of the early history of this enterprise illustrates my point: Two of the original participants, whom we will call "X" and "Y", participated in the performance of the enterprising function at the inception and through a period of the development of the enterprise. At a later period they decided that under the conditions as they were developing they would withdraw from it. Thus it represents a continuing or a recurring function. They undoubtedly did not make the decision to withdraw on the toss of a coin or anything of that sort. They undoubtedly gave a great deal of thought to the probable outcome under the conditions as they were developing, and they were performing this selective judgment-exercising function at that time.

If a pipeline were constructed after research and a line constructed without research would have been less economical, you ask me to state who should receive the increased earnings brought about by the research. The answer to that question cannot, in my opinion, be given absolutely and categorically. It involves an amount of economic analysis which is probably to a degree unknown except to those who engage in that sort of refined thinking. The first statement I would like to make is that it depends upon whether the enterprising capitalist envisioned the probable gains from taking these pioneering risks, whether they were entirely fortuitous or whether they were part of his inducement as a first and most fundamental consideration; and secondly, whether or not he viewed these as just sufficiently adequate to make the undertaking attractive to him and interesting in the light of all the risks and uncertainties involved. If he viewed this gain as merely compensatory then he would, if he were asked to put himself in the same position today, view the sharing of those compensations with any one as a reduction in the total probable return which induced him to act the way he acted; and that of course would make the whole undertaking unattractive and uninteresting to him.

1135 I want to make it perfectly clear that that answer is based on the assumption that the return envisioned was just compensatorily interesting to him under the circumstances as they existed. If, as a matter of fact, he envisioned as compensatory an amount which would have been half that much, it might make some difference. All of that is based on this understanding, that the way in which our economic system works under the competitive system, it is normally the fact that a considerable number of people are envisioning the opportunities that exist. It is rarely the case that there is only one person or one group who sees the economic opportunity available in a given time and place. It is only reasonable to assume that these various people who are potential developers of a given situation do not envision it as equally attractive. Thus, to make the illustration a bit more realistic, let us say that there is a group that looks forward to an additional return, on account of this situation, of 5 per cent. There is another group that looks forward to an additional possible return of 3 per cent above. Another one, just for illustration, gets down to finding that if there is a possibility of 2 per cent additional return it looks attractive and interesting to them. There is that competition, and those who are willing to undertake it at the lowest return, normally those who are ready sooner to undertake the engagement, tend to express for our kind of an economic system the best price at which we can get that done at that time. Of course, assuming that there is no monopoly of the opportunity, that there is an opportunity for this competition of the people who are willing to assume these functions at different prices, and that there is every opportunity for free bargaining in every sense to achieve or get hold of this opportunity, the fellow who is willing to work for society for the lowest price, in general and on the average, gets the opportunity.

From that standpoint, therefore, on the basis of those assumptions I should say that it is reasonable to conclude that in the normal working out of the competition for opportunities to invest, the price at which people are willing finally to undertake it reflects fairly the price which society would have to as of that time pay to get that function performed and assumed. If the assumptions there made hold true, then the only possible conclusion is that the marginally necessary compensation for the performance of this function is the socially lowest cost; and if it is such, it ought to go to the people who perform the function. If they were not allowed it and saw that they were not to be allowed it is only reasonable to assume that they would not take on this function. I mean if they were not allowed the incremental return for the exercise of this economic function. That is, in my opinion, a well-established economic thought, that the ordinary processes will drive this return down to the price at which the group that would do it for the least would do it; and that is the group which normally gets into possession of the opportunity. There is, however, as I mentioned, the time element involved. Another group might want to wait longer and should that be the case, if society wants it done then, and we do believe that time is of the essence in the development of improved methods, it is necessary to compensate at the rate at which the most effective or the most economical performance of this function would perform it.

1136 The fact that all of the increased increment of return attributable to design, skill, management and enterprise be allowed the enterpriser who furnished those elements does not mean that the public is denied any benefit from the enterprise just because the public does not receive its benefit in the same identical form. In fact, if society did not benefit and had not benefited from the application of that enterprise principle, the principle would not have lasted as long as it has. The public gets its share and gets it in a bigger and more important way, I think. I reached that conclusion by this line of thought, that if one is to come into a market with a new product or attempts to produce a product in a new way, he is undoubtedly implemented with an idea or a technique which makes him believe that he is going to be able to produce a better product or produce the same product at a lower cost. Industrial history definitely suggests that unless he has some such advantage, unless he can offer the product at a lower cost, or a superior product, or offer it under better service conditions, his chance of success is indeed very slim, that the inertia of customers, the disposition to stay by the products that they have and to use the kind of service they have used, would put up an awful battle, an awful resistance to his succeeding in getting a part of the existing market or service. Consequently, it is implicit in ordinary human behavior with respect to such business that he would only get ahead when he had something to offer the customer which was differentially better. It is out of these improvements and this lowering of costs of production that society has gotten its really important dividends from the enterprise principle. Moreover, suppose it were no better product or not significantly better, or the service were not significantly better, the entering of an established market and attacking the customers of an established business would cost much money and would presumably take a very considerable period of time,—so much so that the ultimate gains on the same technological or economical basis as previously existed would not be attractive or interesting to such an enterpriser.

He has then to really have something differential to offer society to envision any reasonable chance of gain for himself; and society gets its dividends through improved products or lower prices as a result of allowing the enterpriser to believe that he can obtain the rewards for his efforts.

Cross-Examination Interposed by Mr. Staff.

In my previous answer I attempted to state that the amount necessarily allowed to secure the functioning of this kind of a system was the equivalent of the expectation of the marginally necessary return by the entrepreneur. The expectation had to be held out to him. In other words, you had to hold out this much or whatever the amount is, and if it matched his vision as to what was likely to be attractive, that is what he would go to work for. The excess under the strict interpretation of the competitive marginal analysis would be what would be denominated as a surplus or extra gain, but it does not necessarily have anything to do with the gains to society as a whole. He may have had a much better thing than he envisioned and society may have gathered much larger by-products gains. I don't mean by that that he had in mind society's advantage necessarily. I am not imputing any philanthropy to him. Neither am I imputing to society any philan-
1137 thropy toward him. It is usually a stiff, hard bargain, each trying to get what it can out of it, but I

just want to make clear that my answer to your last question did not imply that society would thereby be getting less, but simply that the entrepreneur might be getting more and society might be getting tremendously more. Witness only a few of our striking industries in which that has happened where the possibilities were in no sense realized and where the gains to society today were in no sense appreciated or understood. Both may be in excess, and of course the opposite may also be true, and that is that the expectations of the entrepreneur are not necessarily realized, and he may have been completely mistaken as to whether this would be a benefit to society and they get no dividends either.

If it becomes the understanding of people potentially disposed to be enterprisers that there is to be no allowance of any compensation for the exercise of these functions, they naturally will not be disposed to assume them. Consequently they will not go ahead and attempt to apply new things and new techniques to the development of new products and new markets. As a result of that the progress of our industrial system would be hampered; the disposition to go into these things would be discouraged, and society would lose the benefit of the improvements. More than that, I think it would lose the benefits of the efforts to do the things more economically, which is another result of the operation of this kind of a system. Those who succeed in developing the techniques and methods which economize on our natural resources, which economize on the use of capital, grant a secondary type of dividend and gain to society in that they make these same resources available for alternative employments.

1138 I believe it is important to distinguish between the wages of capital and the compensation for risk-bearing and uncertainty. They are two entirely different things, in my opinion, and have nothing necessarily to do with each each other except that they are commonly associated and commonly met with in the assumption of a business undertaking. Moreover, I believe that risk and uncertainty which I have linked together are to be distinguished.

We find it useful in economic analysis to note that certain classes of uncertainties develop under conditions which give you some kind of an opportunity to forecast or appraise. It is not uncommon to think of a risk as in effect an insurable uncertainty, that is an uncertainty with a sufficiently broad or well established probability basis or experience base so that there is some possibility of appraising the element of risk. The distinction, I think, could well be made by an illustration drawn from the insurance business. An insurance company spreading its risk over thousands of lives, has the guidance of an actuarial experience which reduces the necessary compensation which has to be offered for the chance of death, for example, to a determinable risk, a relatively measurable risk. So any type of business uncertainty with respect to which there is a sufficient experience and background such as an industry in existence long enough and employing a technique well enough known to have been tested, thereby becomes more a matter of the risks involved, because you have got some sort of an actuarial background even though you do not have the kind of thing that the insurance company has access to.

I would like to contrast an uncertainty with a risk by using the same illustration of the insurance company. An actuarial record is based on the past. It is still possible that an insurance company will experience a loss out of line with the actuarial basis on which they have calculated their risks. Consequently, there are the chances of loss over and above the calculable or approximately calculable risks which have to be recognized; and those we choose to distinguish as uncertainties, indicating by that distinction that they are simply hazards which are as yet so new, as yet so rarely experienced, that we have no good basis for bringing it down to more approximately measurable quantities.

In a more practical sense, what I mean is this. The ordinary investor gets used to industries and the characteristics of industries and he establishes something of a measure or opinion as to the degree of risk involved. You approach him with an opportunity for investment in an industry in which no such experience may exist and he is inclined to look at it in the nature of a gamble.

This investment has elements of such uncertainty in it. Although uncertainties are not readily reflectable in the ordinary range of risk compensations, I think it is rather important to distinguish those two when you are dealing with an industry which has such outstanding characteristics that the element of uncertainty is even of more importance than the element of risk as the latter term is defined in the specialized sense.

I did not mean to leave the impression that loan interest is all of the rate of return to which an investor is entitled. I thought I had clearly testified initially that the return could be divided into two important elements: one,
1139 loan interest, and two, the return to enterprise over and above loan interest. What we have been concerned with here is the break-down of the loan interest element only and I did not mean to imply at all that the loan interest is synonymous with necessary supply price of the capital for an industry. If you were to restrict or conceive loan interest as synonymous with the return, there would be no inducement to be other than a lender. That is the implication of loan interest.

This additional compensation is what I have in mind as the compensation for enterprise. The compensation for being a borrower rather than merely being a lender, the compensation for assuming a position of gatherer of loan funds, if such are needed or are available constitutes this additional compensation. Whether an individual chooses to take that position depends upon the sum total of the economic and I might add political circumstances prevailing. Under many conditions, he chooses to sit back and let somebody else do it, that is, he will say let somebody else be the enterpriser and let him use my money under proper protective conditions, but I do not see fit for the rewards apparently available to take this pioneering position of performing the enterprise function and employing other people's capital under the rigid terms which they are disposed to impose upon me. There is not anything new or peculiar about that observation. It has been regularly accepted and observed in regulatory practices that the return has been something more than loan interest.

The natural gas industry appears to be a relatively young industry with a distinctly changing technique, an industry which seems to offer the promise of further expansion and public service, one which because of these circumstances appeals more particularly to the enterprising capital and enterprising capitalists who are willing to assume the hazards of this kind of an undertaking. The enterprising capitalists would not be satisfied with loan interest, or for that part, in my opinion, with a fixed and rigid rate of return. It just is not in the nature of true venturesome capital to engage itself on a cost of service contract.

In my opinion, the public utility industries have not prospered and grown under a system of regulation of the profits. In a very considerable part, the industries classified as public utility industries had their very rapid growth and development during an era in which the regulatory process was still relatively approximate and loose in its application of what we understand to be the regulatory formula. Enterprises in those industries during the 15 years of the most rapid development still had the idea that there was a chance of an enterprising profit. I had in mind roughly the 15-year period in which the electric industry doubled in each five years, say 1924, 1929, or 1930 something like that. That despite the imposition of regulation as a legal fact, entrepeneurial investors still persisted in the belief that there was a chance for an enterpriser's return in those industries; and as a matter of fact the regulatory process was not imposed with the rigidity which the regulatory formula would imply in all of the states of the United States throughout the period of development and growth of these utilities. Item after item has been added to the range of regulatory function, additional authority has been granted, commissions got themselves organized and oriented and gradually got to work. It took a very considerable period of time before the theory of regulation started to approach the fact, and I say that advisedly, of a rigid application of what we understand to be the regulatory formula.

1140 Consequently, I answer that question with some assurance that I do not believe the traditionally regulated public utility industries grew, as they did grow, under the system of profit regulation. They did believe that there was a chance for the enterpriser's profit, and as that prospect narrowed somewhat, the holding company era of activity became apparently a part of the frontier in which there was still some chance of the exercise of the entrepreneurship and the gaining of such an additional reward.

It is only in relatively recent times and still in relatively restricted quarters that there is an increased warning to the entrepeneurs and investors that this regulatory formula is going to be imposed with increasing rigidity, precision and exactness, and it is that in my opinion, which is primarily making the investors feel that there is not going to be any chance for an adequately compensatory return.

I have not looked at the figures recently, but a few years ago was rather amazed to find that somewhere around one-half of the operating electric utilities were recorded not to have any taxable income. (Objection by Commission Counsel overruled.)

As I remember it, it was one-half in number rather than in capacity. I have not had occasion to look into the question of the proportion of the invested capital in that industry which was involved.

In my opinion, the imposition of a style of regulation which was developed for and adapted to relatively mature and maturing industries, upon a young and growing industry still in the stages comparable to the early stages of these industries now so much more readily regulated, would be a distinct threat to their growth and development. This statement is directed entirely toward the question of how the rate of return should be considered and envisioned in the course of imposing regulation of this kind on an industry.

In my opinion, if there is going to be a regulation of an industry in which it is apparent that there is a large function for enterprisers to perform, which is an industry still in the state of development and in which those social results may be looked forward to from the function of the enterprise, then all I would want to say is that the responsibility for properly rewarding and encouraging that enterprise definitely falls on a regulatory authority and it will have to assume the responsibility of keeping the enterprise properly fed, clothed and alive, if it desires to keep enterprise alive in an industry of this sort.

I believe that if the mature and rigid formula of regulation is imposed on an industry in its teen age that it will discourage its growth and development and that the way in which that can be avoided is by a proper and appropriate recognition of the reward for the disposition to be enterprising. (Objection and motions to strike above testimony by counsel to the two Commissions overruled and denied.)

I am conscious of the distinction between a past investment and investment still to be made. A past investment is helpless. That commitment has been undertaken, but its alternatives after it has sunk itself in a fixed and helpless form are very different from what its alternatives are at the time when it is still free to make a choice.

1141 Consequently, my concern is not with respect to the helplessness of a particular commitment but rather with respect to the effect such treatment of past invested capital will have upon an enterprising capital still available for investment in this kind of an industry, given attractive returns. Putting it another way, the only protection which past invested capital really has is the necessity of meeting the terms of capital which is still footloose and fancy free. I think it is a matter of increasing importance because of the increasing scope and range of regulatory activities. The power of an industry to command more capital is pretty largely measured by the treatment which past investments receive within those limits.

Presumably, we are still relying upon a system of individual enterprise and initiative as distinguished from a system of state socialism or communism; and while I am not passing my judgment on alternate systems, if we choose to operate under this kind of a system, it seems perfectly obvious that great reliance should be placed upon the adequacy of the stimulus offered to enterprise.

Cross-Examination Interposed by Mr. Slaff.

By the use of the term "presumably" I meant to indicate that we are aware that in this country as never before there is an enlarging opinion, or let us say sympathy, with some of the foreign ideas such as state socialism and communism, but as yet we seem to be on, let us say, the alkaline side in the equation and relying predominantly on a system of private initiative and enterprise.

Direct Examination by Mr. Morgan Resumed.

To me there is a distinction between rate regulation and profit regulation. I believe you could have rate regulation without reaching the point of rigid profit regulation. I do not believe it follows that you can not have regulation without inappropriate discouragement of enterprise, if I may say so. I think there is a wide difference between imposing restraints on private action and conduct in public interest, and the extreme, for example of imposing the rigidity of the public utility regulatory formula in an effort to regulate. It is to be observed that more and more industries are being subject to regulation. My expectation is that this range of industries subject to regulation is going to increase.

I think it distinctly in error and represents rather careless transposition to assume that every industry that is going to come under regulation is going to be put under the scheme of regulation evolved as more or less suitable to the public utility industries. I think in fact that anyone concerned with the desirable development of a system of public regulation would have in mind that the same suit of clothes is not likely to fit effectively any kind of industry and every type of circumstances. I view distinctly with alarm the disposition to take one suit and measure and impose it upon a given industry, irrespective of its characteristics. (Objections by counsel to the two commissions to the testimony with respect to "views" and "alarm" overruled.)

The fundamental of the public utility formula of course is the traditional concept of a fair return on the fair value of the property used and useful in the public service. When that principle was first enunciated, its meaning and implication were of course not at all clear. It has had a considerable period of development in the minds of people who have engaged in regulatory practice and of course in the minds of the courts in subsequent opinions following the opinion of the Court in Smythe *vs.* Ames. In my opinion, the particular value of the court's opinion in Smythe *vs.* Ames—understand that this is from the standpoint 1142 of the economic consequences—was its comparative tolerance, its lack of rigidity and fixation, in fact the very thing which a great many people complain about with respect to the attitude expressed by the court in that particular case. What I mean to imply by referring to the rigidity with which that formula is now being increasingly envisioned with respect to the more mature industries under regulation, is the idea that rates are necessarily fixed at a level which does not allow the enterpriser to envisage the possibility and likelihood of profit in the traditional sense of a possibility of profit.

As a matter of economic experience it does not always follow that the gains for which an investor hopes in enterprise are actually realized by the enterprising investor. Definitely, expectation is one thing while realization is another; and I have expressed my opinion, I believe, very clearly that it is expectation which functions in our kind of an economic system. In fact, we observe that it is not the number of failures in an industry really that discourages people from going into that industry, it is rather the conclusion that no one has a chance to make a profit in a particular industry that discourages them. If the possibilities of profit and gain appear to be there, the amount of disillusionment which comes with realization does not seem effectively to destroy the disposition to be enterprising.

As a matter of fact, if every investor realized all that he expected when he invested money in a given type or class of industry, it would cease to be a risky industry. It could not then involve such a degree of risk and uncertainty as to call for the exercise of the entrepeneurial function if such were the results.

The idea that I am trying to express is not new or novel or unique in any sense. I was reflecting merely what was in my opinion the accepted economic premise with respect to the relationship. In fact, it is an idea which is about as old as organized economic thought and as far as I know has not been successfully challenged throughout the evolution of economic thought. I would like if I might be permitted just to quote a classic paragraph from Adam Smith, the first of the economists, on that particular point:

"In the greater part of mechanic trades, success is almost certain; but very uncertain in the liberal professions. Put your son apprentice to a shoemaker, there is little doubt of his learning to make a pair of shoes. But send him to study the law, it is at least twenty to one if he ever makes such proficiency as will enable him to live by the business. In a perfectly fair lottery those who draw the prizes ought to gain all that is lost by those who draw the blanks. In a profession where twenty fail for one that succeeds, that one ought to gain all that should have been gained."

The successful hazard-takers do not gain all in the operation of the economic system. The evidence is perfectly clear on this point. They do share the difference with society. If I may finish that quotation from Adam Smith, he went on to say:

"The chance of gain is by every man more or less overvalued and the chance of loss is by most men under-valued, and by scarce any man who is in tolerable health and spirits valued more than it is worth."

1143 The point of that observation is being increasingly appreciated in the operation of our economic system in that the disposition to be optimistic on the part of human beings leads in general to overvaluation of the chance of gain; a willingness to take the risks and hazards for less than their mathematical chance.

I would say that prior to regulation, the natural gas pipeline industry and the natural gas industry as a whole were subject to both large losses and possibly large gains. The history of this industry is strewn with cases of loss which make it clearly classifiable as an industry in which many may lose, and apparently from the records, some can make substantial gains.

In my opinion, if the principle of regulating the rate of return or the power to regulate the rate of return implies the refusal to recognize the necessary compensation for assumption of an enterpriser's position, it would clearly discourage the flow of capital. In a gamble in a lottery in which there may be gains but the gains are small and rather predictable, there is not going to be anyone who is going to very freely take any large hazards and risks; and it seems to me that this goes back to the principle which I tried to explain earlier, that it merely involves the adequate recognition of the innate characteristics of this industry to offset the very probable investor reaction to the imposition of regulation.

In my opinion it is entirely inappropriate in the sense that it does not meet the economic necessities of the situation to assume to transpose rates of return which are appropriate for the characteristics of an industry such as the electric or water industry to the natural gas industry. There may well be something to be gained by studying and observing the behavior of investors under a given type of bargaining under a given rate of return, but to make an easy casual transposition of rates of return that are more or less traditional in one type of industry to an industry whose characteristics are very different will not get the desired economic results.

Even among those utilities which are of the character I have described as being on a more permanent basis and which will continue on indefinitely, the rate of return allowed in one instance is not necessarily the same as in other instances. From my study of the rate of return determinations, it seems clear that earlier in the history of the public utility regulation there was a disposition to make rather marked distinctions among and between the utility classes. Urban transportation was frequently recognized as having a different status. It was not uncommon for commissions to recognize the difference between electric and gas companies in the determination of the return. I may say, however, that my following of the more recent tendencies seems to indicate that as these industries have gotten older and have come along under a rather common formula of regulation, that the disposition to impose a more nearly even rate of return has apparently developed. I am not condoning it or approving it from an economic standpoint, but that is my conclusion from observing rate of return determinations. I mean that reference to other rates of return is not a useless point of reference, but nothing more than that for the moment, at least.

What I have been trying to say from an economic standpoint in trying to predetermine the investor's probable re-
action to this industry in allowing his capital to go
1144 into it, is that he is conscious of the distinctly differ-
ent characteristics of this industry. The natural gas production and transportation industry in my opinion does not have the legal or the economic characteristics of a public utility; and I am of the opinion that it cannot as a practical fact make the kind of bargain for capital that a public utility can make. (Objections by counsel to the two Commissions to the above legal conclusion of the witness overruled.)

In my opinion a public utility which engages in natural gas production and transportation and distribution should be distinguished from a natural gas pipeline which does not engage in distribution activities as far as representative risks are concerned. I believe there is no justification for confusing those conditions simply because there may be an identity of physical plant, or there may be an identity of dealing in the same kind of physical product. There are in my opinion public utilities which distribute natural gas. In that sense there are public utilities that are in the natural gas business. I find also that there are public utilities which own also natural gas reserves and engage in what we call the production of natural gas. Some of the gas fields are sufficiently remote to make it necessary for the same public utilities to engage in the transportation of natural gas as well.

What I mean to say is that just because a public utility produces natural gas that it distributes does not in my opinion necessarily make a natural gas producer a public utility. If I may speak to a very simple illustration; a horse is an animal, but all animals are not horses.

Question by the Examiner.

A public utility is an enterprise characterized by certain distinguishing legal and economic characteristics. Those characteristics go to both the conditions under which the service is supplied, and the conditions under which it is produced. We seek for the characteristics of a public utility both in the character of the supply of the service and in the character of the demand for the service. One of the commonplace requisites is a high degree of the control over the market, more or less casually referred to as a monopoly.

Normally the practical economic monopoly which follows from the character of the investment is recognized by the law as a legal status in addition to the economic status. Thus we have on the supplier's side usually and most characteristically in my opinion a degree of control over the market enabling such an enterprise to exercise control over the price to the extent of differentiating in the price and maintaining price schedules which differentiate among classes of markets in which possibly the power to discriminate in prices—and I do not use the word "discriminate" in any inappropriate sense—I mean discriminate in the sense of differentiate—the power to differentiate in prices in the market is probably one of the most fundamental requisites and circumstances prevailing. Some people talk about the milk industry, for example, as a public utility, and one of the reasons why in my opinion it can never conform to that classification might make the answer to your question clearer.

A milk distributing company might even have a substantial part of the market as some of them do in some communities, but it still can not conform to the formula because it does not have such a control over the market as will enable it to differentiate or discriminate among customers. It cannot, for example, successfully engage in differential pricing, it cannot establish the kind of a
1145 pricing structure and rate schedule that a public utility can.

I understand that one large milk distributor once tried that,—he thought it was a good idea to offer a gallon at a differential price. The net result was that that milk company experienced the distinction which I have in mind, namely, Mrs. Jones and Mrs. Green and Mrs. Brown said, "Did you hear about it? You can now buy a gallon of milk at this differential price." So Mrs. Green and Mrs. Brown said to Mrs. Jones, "You buy the gallon, and you sub-retail to us" and the net result was that of course the differential market was broken down promptly and the milk company retreated to the system of prices which it had to employ.

The nature of a public utility however is not to be found merely by examining the conditions under which production takes place. We have to examine in addition conditions under which distribution or the demand expresses itself. This is in looser and easier language commonly referred to as the essentiality of the service, the necessitous character of the service rendered to the people.

It is clear that you cannot have this status by merely having one of the circumstances prevailing. There are many necessities in this world of human beings,—the essential requirements to have food, clothing and shelter, which are probably most necessitous, but we do not assume to put industries providing these essentials in the public utility category, because normally on the supplying side, these services are rendered under the conditions of competition giving to the customer alternatives which make such exercise of public authority unnecessary and impractical.

So in attempting to find a fundamental concept on which to distinguish public utilities, we say that is necessary to view both sides of the equation. We have a coincidence of the two standards, one, the production under conditions of restriction which is for practical purposes the single provider in the single market situation, and on the other side, a necessary or essential product. When you have the coincidence of a control of the market on one side and dealing in an essential on the other side, you have the requisites of a public utility status, particularly if the conditions of service are such that it gives the enterprise control over its product down to the final disposition in consumption, because if the technology of the industry is not such as to give it that control down to the point of final consumption, it can not conform to the economic behavior which we find in a public utility.

Thus in the briefest sort of way, we have the implication of a high degree of monopoly on the one side and an essential service, on the other, which two requisites combine to place the customer in what we denominate a position of dependency.

Direct Examination Resumed by Mr. Morgan.

Every institution affected with the public interest is not a public utility. I recognize an economic distinction between what is commonly referred to as a natural gas distributing company which owns no distribution or production facilities, one which is known as an integrated company owning distribution, transportation and producing facilities, and still a third class which owns only transpor-

tation and producing facilities. Imported economic differences are to be noted with respect to this hierarchy of enterprise. The investment in the distribution property employed under the public utility status, is commonly
1146 regarded as being more secure since it is exposed to
fewer of the hazards of industrial enterprise than an investment in property not so devoted. A public utility which also invests in natural gas production and transportation is investing in an industrial area which is characterized by a larger degree of risk and uncertainty. I believe it represents an exposure to a type of risk that is not common to traditional class of industries recognized as public utilities. I certainly believe that the degree to which the risks and uncertainties are present in this kind of enterprise is unusual and not closely comparable to the degree of risk present in the traditional public utility industries.

The distributing company from an economic standpoint enjoys a practical protection by virtue of the indisposition of any informed investors to place their investments in a duplicating distribution system, for example. And in addition it is rather common to have the law put its seal of approval on that economic fact by the granting of franchises amounting to a legal monopoly on top of what is a rather practical economic monopoly under most conditions.

(EXHIBIT 143 previously offered was received in evidence over the objections of counsel for each of the two Commissions, to whom the Examiner allowed exceptions.)

The natural gas pipeline company subject to the jurisdiction of the Federal Power Commission and the type of utility to which I have referred as enjoying a legal monopoly ought to be distinguished in two respects: (1) A production-transportation company is not engaged in distributing services as a public utility, and (2) it does not, by virtue of an economic characteristic or the legal sanctions granted through a franchise or similar protective device, have a monopoly. It is my understanding that the natural gas pipeline company has not been granted an exclusive franchise of any character whatsoever and that it is possible under the law for a competing company to enter the same markets. I understand that the law is interpreted to mean that if a competing company can offer to render services at lower prices that it may have access to the market.

The three classes of natural gas companies to which I have referred cannot be regarded as being of the same character and as involving the same risk in appraising the rate of return to which they are entitled. I believe there are three clearly distinguishable stages: (1) the public utility distributing company which may be distributing natural gas; (2) a public utility distributing company which may own transportation facilities which bring the gas which it distributes, and (3) a public utility distributing company which owns not only the transportation facilities but possibly also production facilities and natural gas resources. None of these three are reasonably comparable to a company which has only the last stage, either production only, or production and transportation, because in the first three cases we have a public utility which, incidentally, has investments in these other forms, and in the latter case we merely have a company with an investment in the production and transportation facilities.

In my opinion, the natural gas distributing business is a more hazardous business than the electric distributing business because it has to rely upon a supply of natural gas which is exhaustible. I accept it as a matter of common knowledge that natural gas supplies are exhaustible.
1147 Even though a distributing company may have some protection by virtue of the fact that it has a fairly effective economic protection due to the indisposition of investors to duplicate the investment in distribution facilities and even though it may have a legal franchise which gives legal sanction to that status, yet because it depends upon a source of natural gas supply which is exhaustible, I think it introduces a hazard which is not present in a continuing operation such as the electric industry. When the natural gas supply runs out, there are some alternatives open to such a distribution system, but those are not costless alternatives. It may be able to find a source of supply in another direction. It may have to resume the operation of manufactured gas plants and wean its customers back to accepting the prices and limitations of use which ordinarily accompany manufactured gas production. That also is not a costless experience. The customers will not like it and particularly they will not like the readjustment to a different level of cost prices of the rates.

Furthermore, such readjustment period would undoubtedly afford an excellent opportunity for the electric company, which may reasonably be assumed to be present, to further extend its invasion of the service area of the gas industry.

I have had occasion for a number of years to watch the opinion of courts and commissions in matters of this sort and it appears to me that there has been a rather decided observation on their part of the fact that the natural gas industry is fraught with risks and hazards that are unusual and should be distinguished from those in public utilities; but I would like to make clear that I do not recall any such decision which was not dealing with a public utility company that was engaged in the natural gas business and that the distinction between that level and that of a production and transportation company is another matter.

It seems to me that qualitatively the distinction last mentioned would mean that if the public utility company which had a substantial part of its investment in the more hazardous forms of capital and resources were allowed a return which recognized that, then certainly it might seem reasonable that a concern which had all of its investment in that portion which was recognized as more hazardous would certainly be entitled to a higher rate of return. If the investment were, for example, 50-50 as between a public utility distributing investment and a production and transportation investment, and if a natural gas distributing public utility, for example, were allowed a 7% rate of return, and the one which had half of its investment in natural gas resources and transportation lines were allowed an 8% return, then by simple arithmetic we might arrive at the conclusion that the portion of the investment which was in production and transportation had been envisioned as entitled to something like 9% to get an average of 8%.

In connection with my statement relating to the transposition of rates found for an ordinary electric utility over to a natural gas company, I merely wish to point out this: The differences may be of two types: (1) there appear to be some real differences of kind in the character of the risks and hazards involved in natural gas transportation and production, and (2) there was other hazards which are hazards in different degree. I merely meant to draw the conclusion that the significance of unique risk and the degree to which certain common risks and hazards were present here made it difficult if not impractical to engage in that kind of a ready transposition of rates of

return from a public utility situation to a gas pro-
1148 duction and transportation situation.

I am not at all convinced that a recognition by the regulatory bodies of the necessity of holding out the possibility of increased reward to enterprising capital would result in the public's paying more for the service that it would in the case of a public utility. In fact the burden of much of my testimony up to this point is to the effect that they probably will not pay more. I am of the opinion that in the industries where risk and uncertainty play such a large relevant part, the imposition of a fixed or limited rate of return may actually result in a higher overall cost of the service. That was the point and burden of the discussion on the willingness of people to overvalue the chance of gain, the disposition to take a gamble where there was a possible compensatory return. I am convinced that people will receive service at a lower price under certain circumstances when we rely upon the disposition and willingness of the enterprising capitalists to take the chance, than they would otherwise. To put it in another form, I think there are conditions where a regulated industry actually develops a higher cost of capital than an unregulated industry. In fact, it is not an unusual observation at all to note that the industry where there is the largest chance of gain actually averaged out at the lowest cost of capital because of willingness to accept the risks and hazards that were so great in the light of an inducement in the form of the possibility of something extra in the way of a return.

Personally, I have been of the opinion for some time that the cost of capital to public utility enterprises was probably unduly high compared with the circumstances actually prevailing in those industries merely by virtue of the fact that under the circumstances in which that investment finds itself we do not make use of the capacity to get responses from this profit-seeking motive. It does not necessarily follow that the cost to the public is going to be more because latitude is allowed for the inducing of capital.

What I mean to say is that they will probably receive service at an earlier date, will stand good chances of receiving more adequate service at an earlier date, and there is distinctly the possibility that there will be a fuller exploitation of the opportunity if something is held forth as an inducement to capture this capacity of human beings to respond to the possibility of an extra gain. (Upon objection of company counsel examiner strikes statement of counsel for Illinois Commerce Commission to which objection is made by counsel to the two commissions.)

When I stated that it does not follow at all that the cost of the service will be increased by allowing compensation for enterprising capital, I meant to express the opinion that there is something valuable to capture and to exploit in the performance of the enterprising function, that if enterprise is induced to perform efforts will be made to find more economical ways of performing the services, the services may be rendered more fully, will probably be rendered more adequately and a wider range of uses will be sought out, and the result of the whole will be to contribute to a larger measure of economic well-being and at no necessarily higher costs than would otherwise maintain.

In arriving at the proper conceptions of these hazards, I have exposed myself to a great many sources. I have examined the literature of investment and security analysis to determine what general attitudes were being expressed with respect to natural gas investments. I did this in the belief that it has a practical significance, because what investment analysis and investment opinion is about capital to be put in these industries reflects itself through their advice and counsel, through their published opinions and finally gets down to the investor, and, whether they are right or wrong, they influence the investor's
1149 opinion and react with respect to his investments.

There is a literature that is particularly concerned with the questions of analyzing the relative desirability of investments. I have a few available expressions of opinion from the authoritative publications in that field, dealing with the subject of natural gas securities. These I consider generally accepted and rather widely used and they may illustrate what the opinion is in these matters. They are taken from books and sources that are in general circulation among the investment public, investment counsellors and economists and others who are interested in informing themselves on that subject. I have taken recourse only to those who have some standing as authorities and are widely used and are significant in that they are influencing investment opinion.

One of the classic treatments on investment is the text by Hastings Lyon, Counsellor-at-Law, New York City, and lecturer on Finance, School of Business, Columbia University, entitled "Investment", published by Houghton Mifflin Company. Another source is entitled "Investment Analysis" by Walter Edwards Lagerquist, Professor of Finance in Northwestern University, published by The Macmillan Company. And still another is a volume entitled "The Principles of Bond Investment" by Lawrence Chamberlain and George W. Edwards, published by Henry Holt and Company. Then there is "Principles of Investment" by J. E. Kirshman, published by A. W. Shaw Company. Also "Investment Principles and Practices" by Badger and Guthmann, published by Prentice-Hall, Inc. Another volume "Jordan on Investments", also published by Prentice-Hall, Inc. Another volume "Investments and Investment Policy" by Burtchett, published by Longmans, Green and Co. and "Security Analysis" by Graham and Dodd, published by McGraw-Hill Book Company, Inc.

I have gathered together whatever I could find on the natural gas industry in these treatises for convenience. I have a photostat of the pages which seem to have a bearing on the natural gas industry.

(At this point counsel presented to the reporter a document composed of approximately 12 pages of photostated material of treatises with the request that it be marked for identification. At the direction of the Examiner the document referred to was marked Exhibit 151 for identification.)

In addition to those authorities from which quotations are set out in Exhibit 151, there is one authority which I found since I had this exhibit prepared and no quotation from which is contained in the exhibit. I believe the reproduction of pages 396, 77, and 78 from Graham and Dodd's "Security Analysis" was not reproduced in the exhibit. I can read what it has to say in the record, if you wish, or I can provide a copy, if you wish.

(All of the following testimony of Dr. Doran from transcript page 5686 to transcript page 5721 was admitted over the objections of counsel to the two commissions.)

I have stated that these quotations are part of the literature that goes with the investment business and which is consulted by those who are interested in informing themselves concerning investments and investment practices. I did not consciously exclude any that I thought

had any substantial currency or were at all widely
1150 used. Every good library of commerce and finance would have those texts, I am quite sure.

Questions by the Examiner.

I am well acquainted with the literature in this field. I have advised investors. I have taught courses in finance. I have used some of these volumes as textbooks, and I am aware of the relative standing of these texts. I have advised publishers with respect to textbooks in these fields, and I consider this assembly here a selection from the top of the list. There are less known items available that could have been gathered if you wanted to make the record voluminous. There are privately published things which the publishers did not see fit to touch; but these are the volumes which from time to time, are the popular ones used in schools of business and commerce for the training on investment analysis. These are the volumes you will find on the shelves of investment analysis offices and represent, in my opinion, the best of the literature that is in comprehensive textbook form. It is more than a cross section of the literature. It is the best of it, in my opinion.

My opinion as to the value of it is that here we get evidence as to the general attitude on the natural gas industry as it flows down through various layers and finally gets to the investor. Somebody is approached on the matter of investment in the natural gas industry and the fellow has never had any experience in the natural gas industry. He probably pulls down "Jordan on Investments" or Graham and Dodd, or something else. These are, in my opinion, the best and most generally available. My point was these opinions are influencing, because they are the widely used ones. These volumes even reach deeper into the fabric of opinion than that. They are the ones which shape the opinions and attitudes of the investment analysis people as they are being trained and developed. I cannot from memory say that I agree with every conclusion set forth in these quotations. I do not offer it as to that. This is the type of opinion which is influencing the attitude toward natural gas securities. Some of these fellows are wrong, some of them do not know about some things in my opinion, but that is my opinion against theirs.

Cross-Examination Interposed by Mr. Slaff.

There are a lot of other things that influence investors. He is influenced by what he reads in the stock exchange pages day by day, in syndicated columns, by what financial columnists write day by day. I would not presume to exhaust the things that influence him. I meant to add while I admit the full range of the impact on the investment mind from appropriate and inappropriate sources, I certainly resent any implication that the works of men of professional standing, who are devoting their lives generally to specializing in this particular field and who give considered professional consideration to it in formally published works that they are willing to let go out, are to be put in the class with columnists and reporters of the Curb or Market activity for newspapers or things of that sort. I resent the implication that they are to be put in the same class. I have a series here covering a substantial period of time; and I think the record will develop the degree to which the earlier opinions are borne out by the most recent opinions. I do not know whether the opinions expressed by the authors represent the views of the authors today. I have not asked them. In my opinion, Mr. Lagerquist has not changed his mind.

151 (EXHIBIT 151 was offered and received in evidence over the objection of counsel for each of the two Commissions, to whom the Examiner granted exceptions.)

The paragraph on page 384 of Mr. Lyon's work on "Investment" reads:

"This discussion of gas as the basis of investment has been confined to the manufactured product. There are areas in the United States producing natural gas that enters largely into the domestic and industrial life within reasonable transmission distance of the producing fields. Substantial commitments of capital have been made in the development of the natural-gas fields. Limitations both of space and of knowledge make it seem inexpedient to enter on a consideration of any special characteristics of investment in natural gas, further than to say that the asset does not seem susceptible of measurement to the extent of most mining properties, and in this respect to approximate the oil business rather than the other extractive industries. This, however, is not to say that it may not be a perfectly proper field for investment for one willing to consider what the risks may be and to assume such as are found."

From page 390 of "Investment Analysis" by Walter Edwards Lagerquist, I read:

"The great draw-back with the natural gas companies is sudden exhaustion of the supply which may take place at any time. This is especially true where several municipalities use the same supply. Corporations which supply natural gas and do not make provision for the ultimate exhaustion of their gas wells must, of course, lose their original investment."

Also the paragraph on page 395:

"While the same general tendencies are to be found in the earnings of natural gas companies in relation to population, the ratios are entirely different. The tendency for the ratio of margins to increase with the increased output, however, is very much greater in natural gas companies than in artificial gas companies. There are so many variables entering in the control of costs of natural gas that while this tendency is very pronounced in the whole group, there may be wide variations in the costs within each division of companies in the group. But this fact only necessitates an analysis of the other factors used in determining the values of gas companies."

I will now read the sentence on page 380 of the "Principles of Bond Investment":

"In those sections supplied by natural gas there has not existed the same need for higher rates because of increased coal prices, but the exhaustion of supply has frequently embarrassed the producer and has made necessary the installation of artificial gas plants with resulting higher prices."

I will now read the sentence underlined on page 480 of the Badger and Guthmann work in 1936:

"The rapid growth in the recent past of long dis-
1152 tance pipe lines for the transmission of natural gas
from oil fields to the large metropolitan centers has
added new problems for the investor."

At the request of Mr. Booth, I will read the remainder of that paragraph:

"The companies which produce such gas are usually oil companies, but the transportation, which is a major cost factor, is generally undertaken by independent corporations, in which a gas utility may have an investment interest. To the extent that natural gas instead of manufactured gas is sold to the consumer, investment in production facilities may be reduced and the customary plant turnover and operating ratio increased. Since natural gas has greater heating value than manufactured gas, there has been a tendency toward the measurement of gas, not by cubic feet, as before, but by a unit of heating value, the therm."

From page 486 of the same work, I read:

"The greatly increased availability of natural gas at low prices in recent years has done much to enhance the position of this branch of the industry. Since more than half of the sales of natural gas have been for industrial purposes, the fluctuations in demand are sharp. The mushroom growth of many natural gas producers not engaged in retailing, and the low levels to which business activity has dropped, have resulted in a great deal of financial disturbance among such companies. Natural gas companies which sell wholesale to utilities instead of retail to the ultimate consumer should be regarded as industrials with a depletion type of asset rather than as utilities. Very often the gas business is carried on by the same corporation that conducts the local electric light and power operations. While this combination may hinder the type of analysis outlined, it should tend to reduce the somewhat greater investment risk usually attributed to an independent gas company."

I read next from page 158 of "Jordan on Investments":

"Until recently, the great bulk of the gas sold by the American public utility companies was manufactured through the destructive distillation of coal."

"The cost of the construction and operation of the long-distance pipe lines, however, largely offsets the basic saving in production cost. While there can be little doubt that the development of natural gas will play an increasingly important part in the entire gas industry, for many years to come the great markets of the North Atlantic Seaboard, because of the enormous expense of constructing adequate pipe lines from points west of the Mississippi River, must rely primarily upon manufactured gas."

From the next page of the same work, I read:

"A frank appraisal of relative advantages leads to the opinion that securities of gas companies, particularly of those operating in large cities, usually make good investments, although somewhat less attractive than those of electric companies."

"To a degree, the large sums invested in gas transmission lines have been committed despite uncertainties 1153 with respect to potential supply in the wells, to potential market at destination, and to actual cost of operation."

Then on page 160, this language appears:

"From an analytical standpoint, the following comments are offered. These comments refer only to manufactured-gas companies, as experience with natural gas in its present stage of development is too meager to afford reliable standards of performance."

Passing to page 265 of Burtchett's work on "Investments and Investment Policy", we read:

"In natural gas, the supply, method of transmission, distance moved, and potential exhaustion of the wells are to be examined. The great number of variables which enter the costs of natural gas company operation make it more difficult to analyze than the manufacturing gas utility."

"So far as financial structure is concerned, there are few unusual peculiarities. Fixed charges (debts plus preferred shares) ought to be lower in a type of utility in which there is inter-commodity competition (e. g., gas-electricity-oil for heating) than where no such substitute exists (e. g. water). While some investment writers condone fifty per cent of the capital structure in the form of bonds, it has appeared that forty or forty-five per cent would be a better figure in most cases."

"Natural gas companies appear to open to the uncertainty of supply. While some progress has been made in estimating the amount of gas which may be expected from a given well, there is sufficient uncertainty as to raise serious loss risks through sudden exhaustion of gas wells."

I will now read the excerpt from "Security Analysis" by Graham and Dodd, to which I referred and which does not appear in this exhibit:

"Investment Practice Recognizes Importance of the Industry.—This conception has been solidly grounded in investment practice for many years. The threefold classification of enterprises—as railroads, public utilities, or industrials—was intended to reflect inherent differences in relative stability and consequently in the coverage to be required above broad interest requirements. Investors thought well, for example, of any railroad which earned its bond interest twice over, but the same margin in the case of an industrial bond was ordinarily regarded as inadequate. In the decade between 1920 and 1930, the status of the public-utility division underwent some radical changes. A sharp separation was introduced between light, heat, and power services on the one hand, and street-railway lines on the other, although previously the two had been closely allied. The trolley companies, because of their poor showing, were tacitly excluded from the purview of the term 'public utility,' as used in financial circles, and in the popular mind the name was restricted to electric, gas, water, and telephone companies. (Later on, promoters endeavored to exploit the popularity of the public utilities by applying the title to companies engaged in all sorts of businesses, including natural gas, ice, coal, and even storage.)"

The book from which I read the last quotation was
1154 published in 1938 I believe.

It is very disappointing to find so little attention being given in the best literature on investment analysis to the investment problems of the natural gas industry. In general, the authorities seem to view this industry as affording little opportunity for investment as such—I use the term investment in a restrictive sense as distinguished from the assumption of business risks and undertakings. The authorities seem to feel that general advice and counsel in the matter of investment in the natural gas industry is too dangerous to be offered.

Such expression definitely affects my judgment in arriving at the rate of return for this company. An industry which gets that kind of a lack of recommendation is an industry which, from an investment banking standpoint, would be considered as having additional difficulties facing it in raising money. It would be considered at a disadvantage.

This discussion goes to the natural gas industry of which Natural Gas Pipeline Company of America is only one company.

I have examined the treatment given natural gas securities by Moody's Investors' Service. I consider that as a recognized publication and I know that it is very extensively circulated. I was interested in determining what the experience of natural gas securities was with the rating process which Moody's engage in, so I went through the Moody manual, identifying the natural gas companies, excluding the concerns which were only local public utility distributors of natural gas, and I found 87 issues of companies engaged to various degrees in the natural gas industry, with the exclusion that I have indicated. I think I examined the 1938 volume which was then the latest one available, the 1939 volume having come out in August, or a little later.

I found that Moody's assumed to rate only 32 of 87 natural gas issues. Out of these 32 issues which were given rating, only two were rated Aaa. Aaa rating is Moody's highest classification. I found no issues rated Aa, but I found three issues rated A. The 27 remaining issues which were rated were all rated Baa or less. In fact, the largest number of issues rated were found in the Ba classification, the next to the lowest rating.

The distinction between companies engaged in the producing and transporting operations only and those having a broader field of operation is sometimes somewhat difficult to make; but I believe there were 18 securities which could be classified as being those of companies engaged in production and transportation. Of these 18, only 6 were rated, and of the 6 that were rated, three received Baa rating and three B rating.

I have attempted to make a study of the experience of investors in natural gas investments and investigated the receiverships among natural gas companies during the period 1930 to 1938. The basis for that study is the recording of companies in receivership in Moody's Manual, and I found there were 29 natural gas operating and holding companies,—excluding again public utility companies engaged only in the distribution of natural gas—that were in receivership during this period 1930 to 1938. I attempted to ascertain the bond capitalization of these natural gas companies in receivership during the period 1930 to 1938 and found that the amount of bonds outstand-
1155 ing at the time of the receivership, or the last report available before the receivership, was in excess of $125,000,000. Then, in order to see what the significance of such a figure might be, I attempted to get a basis for comparison in the bond capitalization of all natural gas companies of these classifications that were found in the Manual on which there was a report. I ascertained that to the best of my ability and found that the debt capitalization in receivership represented approximately 24% of the estimated bond capitalization of all natural gas holding and operating companies of the classification indicated above that was publicly outstanding. Of the total bond capitalization in receivership, $90,878,000 was applicable to operating companies and the remainder of $34,566,000 to holding com-

panies, thus the ratio of bond capitalization in receivership of the holding companies was 30% and for operating companies 22%.

I also found that 17% of the estimated preferred stock capitalization of operating companies of the above classification was in receivership during this period and that 5% of the preferred stock capitalization of holding companies of this class was in receivership, representing, for holding and operating companies together approximately 9% of preferred stock capitalization in receivership.

The investor experience, whatever the causes might be, certainly influences the attitude of other investors. An industry that has a substantial percentage of bond capital in receivership would not be viewed as very attractive. In fact, the financial position and condition of industries is often considered in light of the amount of the industry in receivership. Thus, the railway mileage in receivership is a rather common factor that is published and given attention. For years, the problems of the urban transportation industry were reflected by the statistics on the miles and capitalization in receivership, as evidence of the bad financial condition prevailing in the industry.

Cross-Examination Interposed by Mr. Booth.

I consider the results of that investigation as throwing additional light on the general financial position of this industry and in that respect upon the reception which securities of a natural gas company would receive. I would say that that was a factor that influenced my opinion as to the kind of a capital bargain that a natural gas company could make. That observation would apply to these companies or any one that was burdened with the natural gas label.

Direct Examination Resumed by Mr. Morgan.

My investigation disclosed that over the 11-year period 1928 to 1938 investors in natural gas operating and holding company preferred stocks were paid dividends of 48% of the stipulated preferred dividend to which they were entitled. The average does not reflect the low level to which the proportion of dividends paid to dividends possible fell during this period. In 1933, 1934, and 1935, only 21% of the required amount was paid. In 1936, 27% was paid, in 1937, 43%, and in 1938, 42% was paid.

The experience of the investors in the operating company preferred stocks was naturally somewhat better; but over the 11 year period they received in all only 71% of the
1156 indicated dividend payable. Their returns also in the depression years fell to substantially lower levels. During 1933 and 1934 they received only 55% of their due, of their preference expectation. In 1935, 54%. During 1936 the percentage paid was 59%, and by 1938, it had risen to 89%.

These figures are compiled from published records, Moody's or wherever we found records to determine payments. The receivership study is based on the scope and accuracy of Moody's reports. The receivership records of Moody's are generally accepted as accurate. The derivation of this is entirely my own. There is no secondary source for that information. I think it is only fair to note, however, that preferred dividends are sometimes passed and made up subsequently; and an objective appraisal of the investors' experience would fall short of what it ought to be if it did not relate the back dividends as they came along. I did that and found that by adding in the back dividends, the investor in natural gas operating company preferred stocks averaged 72¼% of his stipulated dividend as compared with the 71% without giving effect to this judgment.

The significance of this investor experience with natural gas company preferred stocks is made clearer, I believe, if we are allowed to make comparison with the experience of public utility investors with their preferred stock investments. We are well aware that investors have had some dubious experience in recent years, and an absolute figure of 71 or 72% does not necessarily of and by itself mean so much; so I carried the process a bit further in order to get some standards of judgment and measurement. Entirely comparable figures, I was unable to develop. The figures used for comparison purposes are from 1930 to 1936. I think this is justified because there was relatively little disturbance to those relationships after 1936, and that, if anything, by emphasizing the period 1930 to 1936, it puts an electric and other utility companies in a worse position because, as we noted with respect to the natural gas companies, they did recover considerably and were better off in the later years. So despite the fact that I could not bring this all the way to 1938, I feel that the comparison is conservative and it is certainly adverse to the point I believe I am making.

The figures for the seven years, 1930-1936, which do not give effect to the resumption of dividends which took place to some extent in 1937-1938, show that investors in electric operating public utility company preferred stocks received an average of 88% of the stipulated preferred dividend, and that for the same period, investors in gas operating public utility preferred stocks received over the seven years, 1930-1936 inclusive, over 77% of their dividend commitment. Investors in preferred stocks of composite gas and electric operating companies received 96% of their stipulated preferred dividends over the 7-year period. Even investors in the preferred stocks of composite electric and traction operating utility companies fared very well, receiving more than 97% of the preferred dividends possible over the same period. Investors in the preferred stocks of composite electric, gas, and traction operating companies, apparently experienced some of the results of including both traction and gas service, and averaged on a relatively small volume, probably too small to put a great deal of reliance on, nevertheless 72 percent of the preferred dividends possible.

By comparison of these results with those obtained in
studying natural gas companies, the investors in the
1157 preferred stocks of natural gas companies, excluding
again those engaged only in public utility distribution, fared substantially worse than the investors in the preferred stocks of public utility companies.

In my opinion, the most fundamental characteristic which has a bearing on the risk and uncertainty which an investor in natural gas faces is the limited economic life which is imposed on the whole investment by the exhaustible character of the natural gas resources. I do not mean physical life. I accept the opinion of geologists and technologists that there are great hazards with respect to the probable physical supply of gas. That seems to be a matter of sufficiently common acceptance to justify my accepting it. I had in mind, however, what I consider a much greater hazard than that of an uncertain physical supply. I meant the economic life of a natural resource as distinguished from the physical life with which the geologists deal.

The physical life might in the extreme be measured by the time that the last bit of gas was physically exhausted from the ground. Obviously an economic undertaking could never go that far, since the cost of bringing the final supply of gas would be prohibitive. The economic supply consists of that part of the physical supply which has economic significance, that is the part which can be made available at a cost which is equal to or below the price obtainable in the market. Thus, the exhaustion of the economic supply in the case of a wasting natural resource would always be something very much closer at hand than the exhaustion of the physical supply.

It will not pay to exhaust the last bit of natural gas from one's natural gas resources. When we talk about economic supply, we always mean available supply which is really physical supply at a cost.

A pioneering enterprise would certainly involve more risk than an enterprise with a background of experience; and investors would as a practical matter consider it as involving more risk because he does not have the experience basis to go on. Applying that principle to these pipe line companies which built a pipeline system from the Panhandle of Texas to the city of Chicago, a distance of more than 950 miles, the investor who faced the opportunity, if opportunity it be, to invest in that kind of a venture would naturally be concerned with the question as to whether it was economically feasible to transport gas that distance. He would be concerned as to whether continuity of service could be maintained with sufficient certainty to make the enterprise profitable. He would be concerned about the fact that no one else had previously attempted to transport gas at such high pressures over such distances; and consequently, I believe, he would be impressed with the large measure of sheer uncertainty, as distinguished from risk, which exists in the absence of any basis for calculating and establishing an opinion as to the degree of risk involved. I think, however, he would be more concerned with the question as to whether or not it would be profitable to transport gas such distances even though he might feel reasonably assured that it was technically possible.

The major question remaining for him would be whether or not the cost of transporting the gas such distances, the very length of the haul, would not eat up the advantage of bringing the product which is relatively low priced at one point to a market as far away as Chicago is. Certainly, in the absence of any well certified past experience 1158 as to what costs are likely to be, not only immediately but over a period of time in which his investment is helpless and fixed, he would most logically put it down as an investment involving such wide uncertainties as to be beyond calculation as to the appropriate degree of risk to be assigned to it.

Obviously, it is not always possible to know in advance, in a project of this character involving a great deal of technological pioneering, just how it would work out after its projected working out is set down on paper. The economic and industrial history is replete with instances of what seemed to be good technological ideas which did not work out economically.

This was in large part a transportation venture. Transportation is the moving of a commodity from one point to another. This was a specialized transportation investment made for moving a commodity from one rather specific point to another rather specific point, consequently it was under the peculiar difficulty that it had to be entered upon and engaged in as a whole. It had to be built as a pipeline from the source of supply to the only market which was conceived adequate and appropriate to make it an economical venture, consequently no piece meal construction, no approximation of the investment, no trying it out was possible, it had to be a venture where everything was put on one throw, either win or lose, since a half line obviously was no line at all.

From reading the record in this case, I have undertaken to understand the technical difficulties as they have been reported in the record and as they are presented in the records of the inception and development of this enterprise. I understand that the principal technical difficulty which faced the enterprise was to achieve a combination of circumstances in which the investment per unit of transportation capacity could be made low enough so that the difference in price between gas in Texas and gas in Chicago would yield an attractive and compensatory return. Technically, this resolved itself into the development of a type of pipe which had the strength to carry high pressures and which, on the other hand, had a capacity per pound of steel required to transport the volume of gas needed in the Chicago market, and served it adequately on an economic basis. This required a character of materials to be employed in the pipe, a method of fabrication and a choice of proper size to make the undertaking as a whole economical. The pressures at which the gas had to be transported were significant because by increased pressure it was possible to increase the effective capacity of the line. The pressures could only be such extremely high pressures if the strength of the pipe were adequate. Great strength of pipe, however, could not be achieved by merely increasing the weight of the pipe or it would increase the investment per unit of transportation capacity. So it really was a very complicated, industrial economic problem of finding a balance of all these considerations which would make it feasible to engage in this unique transportation service.

I attempted to acquaint myself with the experiences during the period of construction and operation. I recall as particularly interesting the freeze-ups which developed by virtue of the sudden expansion of certain gasses that were ingredients in the gas transported due to the high pressures at which they were being transported. That was a very interesting one to me and I happened to recall it.

1159 I have heard the evidence here concerning the high stresses at which these lines have been operated, and have read the testimony of other witnesses on that point. It is my understanding that whenever one pushes technological processes to their limits, that it brings with it unusual behavior, and sometimes even freakish disturbances. Thus the effort of reaching high pressures brought with it the thing I referred to as the formation of a type of ice. That principle seems to be true in industry in general. As one pushes to the limit of technological performance one reaches a point where the hazards and risks inherent in that technological phenomenon become greater. In fact, the hazards seem to increase more than proportionately after you get up to a certain point, just as the cost of increasing the speed of a ship multiplies more than in proportion with the increase in speed. (Objections by counsel to the two commissions to above testimony overruled.)

Questions by the Examiner.

I was merely expressing an economic analysis, faced with that kind of technological extensions. I do not know the limit of technological advance in the gas transmission industry. If a person is professionally competent to do any kind of industrial economic analysis, he is aware of the fact that as you push technological development further you run into the hazards of performance of that character; and if placed in the situation in which it was represented that there were such pushings to the margin and extremes of technological behavior, he would conclude there were economic hazards not prevalent in a number of operations.

Relatively and comparatively here was an enterprise which was proposing to transport gas at unusually high pressures. From an economic analysis standpoint, if someone comes in with a proposal for financing an enterprise and proposes to conduct his operations within an unusual range of previous technological performance, he is appropriately, from an economic standpoint, looked at, to some extent, askance. This is more in the realm of what might or might not happen. There are unknown things that develop at this stage of intensification. Thus, proposals to transport electricity at unusually high voltages fall within the same class of behavior.

Direct Examination Resumed by Mr. Morgan.

From the investors' standpoint, the technological phenomena, of course, are primary, but they are not appropriately viewed as final or determinative. The important fact from the investors' standpoint is what the economic result of such technological pioneering would be. The economic uncertainties involved include all the technological uncertainties and independent economic uncertainties as well. Economic uncertainties are concerned primarily with whether or not the difference between the revenue receivable and the cost necessarily incurred will leave a margin constituting an attractive return from the investment that has been hazarded in that enterprise. These economic uncertainties, therefore, express themselves in terms rather parallel to the technological uncertainties. It becomes for economics not a question, can gas be transported from Texas to Chicago; but, can gas be economically transported from Texas to Chicago? At what investment cost can it be transported? What will the operating cost be? More important possibly even that these questions in a final determination as to whether such an undertaking is economical or not is the question as to the size and character of the market required to make it possible to transport gas economically over such a distance.

The question as to whether a market is in size and in demand characteristics adequate is not easily answered. 1160 It is very frequently a question which is answered only by actual trial which may turn out to be error as well. Finally, the question becomes one as to whether the potential market which is assumed to be there and which may be there can actually be captured in a short enough period of time to make the undertaking profitable. If an effort of this sort had to go through a 5-year or 10-year period of inadequate utilization of the investment before an adequate market was finally developed, the income foregone during that period might be so large that the price which the customers in the future would be willing to pay would never adequately compensate the investment. Thus the time factor involved becomes economically important. The market must be appraised in terms of size, the nature of demand behavior, and how long it would take to be able actually to obtain the market which appears potentially available.

I have read the contract between these parties and Chicago District Pipeline Company. The negotiation of and entering into such a contract would not in my opinion overcome the hazard under discussion. While the existence of a contractual arrangement would in all probability stabilize or establish the limits of the experience or rather establish the nature of the experience within said limits, yet ultimately the security behind the investment in a transportation facility of this sort is the security behind the readily available ultimate market. A contract for the delivery of gas on the basis of an amount which the market would not absorb would undoubtedly be subject to revision or compromise by failure of one of the contracting parties to be able, or to see fit, to continue to assume the burdens of such a contract out of proportion to the possibilities of the market. (Objection by commission counsel to above testimony overruled.)

I am talking about a situation where there is a divorce between the enterprises engaging in various stages of production and marketing of a product, and if there is an intervention of a contractual relationship between these two separate enterprises whose interests are not in common in the matter, there still remains a grave economic hazard, namely, that if the terms of that contract turn out to be other than what is bearable under the economic conditions disclosed, that such a contract is not construed to be very much of an economic protection, and it is very likely to be modified to conform to the economic possibilities of the situation.

The fact that under the law, the annual value of the money employed would during the development period be carried into the capital as interest during construction would not as I see it alleviate the hazard under discussion, because, merely capitalizing an expenditure does not give you a return on that expenditure, or return the expenditure to you. Capitalizing an investment is merely recording it in a systematic way so that for appropriate purposes the facts may be drawn off and given the consideration which they deserve. Accounting does not give you a return on your capital, neither do accounting transactions return your capital to you.

The capitalization of that item would operate to increase the amount on which a return will have to be earned if the use of that money be compensated. I did not mean to imply that the interest during the development period of an enterprise is not an appropriate capital item. I answered that question in the exact form in which it came, namely, that capitalizing did not do anything about a return on or of your capital and having it on the books does not do
1161 anything about it. Only if it is recognized that you are to earn a return on it, does anything develop which is of economic consequence.

If recognition be given in the rate base in the form of an allowance for going concern value in an amount sufficient to cover the cost of carrying these facilities which are provided in advance of the loading of the line to its normal capacity, such an allowance does not alleviate the risk and hazard I have been talking about. Merely allowing it in the rate base does not change the fact that a project that is constructed under these conditions and circumstances involves hazards on account of the size, the magnitude, the time elapsed during construction and the other factors. Putting it in the rate base merely establishes the presumption that a return will be earned on it; but if the hazard involved in that kind of an investment is not recognized, then there is no appropriate recognition of the hazard element involved in the development of an enterprise under those circumstances.

1162 Ultimately the security of the investment is dependent on the reliability and the certainty of the income available to pay what we have called the wages of capital. This income or wages of capital we have defined as the difference between revenue and cost, consequently the amount and security of that difference between revenue and cost is dependent upon all of the factors which would influence the revenues of an enterprise or the costs which it would incur. You can think of revenue and costs as blades of a shears or pincers, and the differential which the investor is able to maintain between the two measures the return which he will be able to obtain. Thus his income would be larger if revenues rose and costs remained constant. Thus his income would be larger if revenue remained the same and costs decreased. On the other hand his income might be less even though revenues rose, in case costs rose more than revenue; and his income might be decreased, even though costs decreased, if the revenues decreased more than the costs decreased. There are a great number of relationships there all arising out of the possibility that the cost phenomena may well be independent of the revenue phenomena and vice versa.

To the economic analyst, cost behavior in a pipeline transportation project appears to be highly unpredictable and uncertain with respect to a large number of the aspects of the operation. It would appear for example in the first instance that the cost of an adequate supply of gas is not predictable; that it does not appeal to the economic analyst as being predictable with the assurance that he would like to see; and of course what I mean here is the supply of gas, not the physical supply, but the economic supply that is provided. The cost of a supply of gas adequate to fully economically utilize the pipeline transportation facilities seems to be a highly uncertain matter for the future in an enterprise of that sort.

I do not believe that any economic analyst having any acquaintance with the field of industrial economics would make the assumption that because Texoma owns three trillion cubic feet of gas in a field from which there are hundreds of others producing natural gas that Texoma will ultimately produce that much gas from the field, and through its pipeline transport that much gas to market. In fact I am very certain that he would be disposed and forewarned to consider the question of the cost of an adequate supply or of a reserve as not readily determinable. The rate of economic depletion of such a reserve is apparently not very predictable. I appreciate that the geologist may express confident opinions as to what the physical supply is and what the rate of physical exhaustion may be; but in my opinion that is a long way from giving reasonable assurance as to what the available economic supply will be at a given time. How much of a physical supply will be economically recoverable, I think is a more imporcetant question than the geological opinion as to how much physical supply happens to be there. It involves more uncertainty, in my opinion, than the estimate of the physical supply because it has in it all of the uncertainties of the estimate of physical supply, and in addition the uncertainty as to the cost at which such a supply can be made available, which cost of course limits the economic supply to a fraction of the physical supply.

You cannot get the answer to the question from the production engineer. I would like to add that there are many circumstances where it is probably inappropriate for him to attempt to give the answer. I would say that when
the engineer starts dealing with costs, he is entering
1163 a field which involves considerations for which his
primary engineering training at least does not necessarily as such qualify him. More loosely one might say that he becomes something of a practicing economist when he moves from the field of technology into the field of costs.

I believe that a competent engineer can offer reasonably reliable estimates as to the efficiency at which various volumes and amounts of gas can be withdrawn from natural supply sources. He can, ~~and if experienced,~~ with a degree of assurance, go further and estimate what ~~the~~ costs of production under any given assumptions of efficiency would likely be. But when he adds the assumption of cost to the assumption underlying technological efficiency, he has introduced a second set of hazards and uncertainties; and the experienced engineer will tread with even less assurance when it comes to assuming what the costs will be than when he is dealing with technological and efficiency factors, which are more strictly in the domain of his own profession. Thus, I say that the economic supply, in my opinion, is far less predictable than the physical supply.

An economic analyst in analyzing this kind of an industry is impressed with the fact that property rights in natural resources on the surface do not coincide with property rights beneath the surface. On the surface those rights are defined in terms of area by reference to latitude and longitude; but below the surface there appears to have developed a type of communal ownership where property lines no longer confine and segregate the portions assignable to the defined property areas on the surface. Consequently, the subsurface resources are held in what is in effect a common ownership of all those who have rights to the surface of the earth. This leads to all of the usual economic results of common ownership, namely, an indisposition to conserve or protect the whole in which you have only minor or undefined actual interest. This the economist has recognized for a long time to underly the problem of conservation, and is one of the reasons for the wasting of natural resources, whose boundaries are not definable as the legal boundaries of property ownership on the surface.

(The following testimony from transcript page 5750 to page 5758 was admitted over objections by counsel to the two commissions.)

I had occasion to read the Federal Trade Commission record on the natural gas industry. I recall the discussions of the Government investigators with respect to the wasting of resources down there and the reasons for it. Some months ago I read a fairly elaborate record of the vacillating conservation policies in the State of Texas, and the efforts at legislative modification of legal relationships arising out of this particular situation, and I beg to say that I am not unaware of the considerations falling within the field of what we call resource economics. I went that far back in trying to form the ground work for an opinion. I gave consideration to this specific question in arriving at my judgment as to what was a proper rate of return. I was quite alarmed about threats to impose a common purchaser status on the pipeline industry arising out of the disgruntled condition of many of the owners of those natural resources. I think it is something that cannot be overlooked. It is well understood that the owners of rights in communal property are not impressed with the same considerations of conservation, with doing the most economical thing with those resources, as if there were individual and exclusive ownership. It is only the natural working out of the most fundamental economic instincts and behavior, the effort to get what you can for yourself. There certainly

is no inducement for any one or even a part of the owners to conserve, while others are getting more, to
1164 their economic disadvantage. There is every economic motivation to get yours while the getting is good. When faced with a threat of that kind of a realignment or readjustment in the legal relationship, the economic analyst would view it as introducing additional hazards to the enterprise, first in that there is the chance that it would make useless a part of the existing investment which was adapted and adjusted to the source of supply which was envisioned when it was undertaken. On the other hand, the necessity of investing more money in additional facilities would not be viewed favorably, because that would be merely adding to the investment and thus increasing the base under circumstances which are far from attractive from the standpoint of a well conceived, well balanced system, and dictated by considerations of the law rather than considerations of industrial economics.

It may well be that fairly accurate estimates under present assumed conditions could be developed as to the probable minimum cost in the way of capital outlay and operating costs of producing gas and transporting it over a long distance such as that between the Texas Panhandle and Chicago; but all that the economic analyst would be disposed to rely upon in a venture of this sort would be that the nature of the project is one which gives rise apparently to increasing costs. The rate at which these costs will increase involves many uncertainties in that although minimums might be estimated, the possibilities or probabilities of exceeding these minimums are sufficiently great so as to preclude any attempt at forecasting what the future probable cost will actually be.

(October 6, 1939.)

Questions by the Examiner.

I have given the question of depreciation of public utility properties and depreciation behavior a great deal of attention over the last 10 or 12 years. I am not uninformed as to the nature of depreciation of property nor its causes. I have read a great deal on the subject of depreciation behavior in public utility cases, and I am familiar with the physical phenomena which gives rise to depreciation. In my opinion there are fundamental similarities applicable to depreciation of the properties of natural gas companies and the properties of other utilities, and there is one major distinction. I have studied the characteristics of the natural gas industry with a view of determining what peculiarities there are in that industry which would make the phenomena of depreciation other than it might be in a property such as an electric or manufactured gas company property.

The distinction which I would like to make between the natural gas enterprise and the utility enterprise is one which arises out of a relatively simple matter of distinction and observation which I think can be drawn without getting involved in any of the technical details. I accept it as common knowledge and accepted fact that the natural gas industry supplies are exhaustible. That distinction carries through in an important way in its influence on maintenance and depreciation behavior.

Direct Examination by Mr. Morgan Resumed.

It is not expected that the maintenance and depreciation
expense, and by depreciation I mean physical depreciation,
will continue during the later life of physical properties
such as are employed in a natural gas company at
1165 the same level as during the early life. As an eco-
nomic analyst, I would not assume that costs in-
cident to maintenance and depreciation would continue at
the same level during the later life of a property of this
sort as before. I mean a natural gas property, the entire
undertaking because economically it is interdependent.
The transportation facilities are dependent upon the
economic life of the gas field, consequently it would apply
to the entire investment.

I am speaking of the physical properties as distinguished from the natural gas itself, although the exhaustibility of the supply underlies the entire phenomena. The economic and financial analyst is impressed with the fact that the property depreciates more rapidly as it reaches an older average age. This is a commonplace phenomena, in fact something that everyone experiences with respect to the technical behavior of properties and goods that he employs and uses. It clearly seems to be the fact with respect to composite industrial properties.

The distinction with respect to a natural gas property which I wanted to bring out was that in an undertaking of a limited life, the most economical way of taking care of maintenance and depreciation is not the same as the most economical way of taking care of maintenance and depreciation in a property of assumedly unlimited life. The reason for that principle is this, that whether or not it is profitable to make retirements and replacements or to spend large sums for maintenance is determined in part by the length of time over which you expect those retirements and replacements to continue to serve. To put it in simpler language, a house owner does not wisely or economically repaint his house the year before he is going to tear it down, as a normal experience. The expected termination of the enterprise as a whole, therefore, leads to deferring more and more replacement as you approach the final termination of the enterprise as a whole.

As a result of that economic disposition to defer replacements as you approach the termination of the project as a whole, the average age of the composite property of this kind of an enterprise tends to rise, because you do not reach that normal life cycle of replacement which you do in a property of unlimited life. The economical thing to do is to defer or not to engage in retirements as you approach the end. Assume that you reach within 3 or 4 years of the end of the life of the property, and it would be economical to make a replacement of an item of property under normal conditions, but the item of property that you would replace is one in which you would have to buy 15 years of future use. To buy the 15 years of future use for a probable 3-year life is more uneconomical than to suffer with the existing equipment, consequently there is the economic disposition not to engage in the replacement at all and to suffer the higher operating and maintenance expenses during that time rather than add to the capital investment, all of which operates to raise the average age of the property.

Industrial economists usually follow the alternative of suffering with a higher maintenance expense rather than making a retirement and a replacement and incurring higher capital costs. The problem of the industrial economist as a manager is to choose between suffering that higher maintenance expense or the capital expenditure of replacement—whichever is the least expensive for the operation.

1166 In a property of unlimited life you would not hesitate about choosing to make a replacement, because you would expect to be able to use up that replacement over its life, and then it would be economic; but as I pointed out, if you had only 3 years more to go on the whole, you are not going to be disposed to invest in a 15-year life to eke out that 3 years unless you technically have to. You would choose to suffer with the higher cost of using an older depreciated unit of property, not that it is so efficient, but it is more economical than to suffer the waste of capital involved in reinvesting in long life property. That is a fundamental distinction between an industry with a terminable point and an industry in which it is presumed you will go on indefinitely.

A depreciated facility costs more to operate as a normal experience. A depreciated facility will involve you in greater maintenance expense. You experience it with respect to an automobile or with respect to any kind of physical property. When I am reaching the point that I am unable to use an automobile any more I probably would not be disposed to buy a new automobile even if my depreciated vehicle might be using a tremendous amount of gasoline and a lot of oil, and might be requiring a lot more maintenance, because I would well consider that a less wasteful experience than to take on a new car. The automobile illustration cannot be carried too far out, because presumably an automobile has an alternative sales value; but a property of this sort which has a fixed and specialized use, which is specialized for its purpose and which has a physical life in many of its units far in excess of the economic life, and which is immobile, has no such alternative application. This is a factor which I think is unique with respect to this kind of an undertaking, and I took it into consideration in arriving at a rate of return for these companies. The testimony here has been recently concerned with the reasonably anticipated behavior of costs, the character of the probable future cost experience, which is, as I indicated, one of the fundamental factors to be considered in the problem of the probable wages of capital that can be earned in the future. Whether or not an investor would be willing to put his money into a project of this kind on the assumption that taxes would remain level, I would say depends in part on how informed the investor is and to what extent he seeks information. I could appreciate that there are small investors who might be approached by a security salesman who would not have the basis for judging a phenomena of this sort. That is not the kind of an investor that should be interested in investing in a pipe line from Texas to Chicago. I merely wanted to qualify my answer by that understanding in the next instance. The informed analyst would be rather hesitant to accept any estimates based on the assumption that taxes will remain at the present levels. He knows that the trend of tax levels has been rising and continues to rise. He knows that there is not much in the offing to suggest that there is going to be any change in the trend of taxation. On the basis of past behavior and present outlook as an economist, I would be very skeptical of estimates which assumed that taxes are going to remain at present level. (Objection by Commission Counsel overruled.)

The record shows that these pipelines have been operating for the last several years at a very high load factor—for the last three years prior to 1939 at 92 per cent or 93 per cent of the total estimated or rated capacity. From an economic standpoint, any enterprise which has to produce its wages of capital, its income, by an intensification of its utilization factors is considered as being involved in hazards which would not be present if such were not the case. To put it in simpler language, a dollar of income earned as a result of high load factor and intensive use of the plant and facilities is, from an economic standpoint, a dollar earned with much greater risk and uncertainty than one which is the result of merely taking the cream of the market at a higher average margin of profit. Any intensive exploitation of a market leads to hazards which are not present in taking the more readily available and the more certainly retainable portion of the market. The lower rate of utilization by just taking the more desirable classes of customers or the more desirable classes of business does not introduce the hazards of the marginal customers
1167 dropping away from you, and does not introduce the hazards of the marginal business of the customers in general dropping away from you. In the case of depression these marginal customers are likely to be the first to go, and the marginal uses are likely to be the first to be given up.

Markets in which the competitive advantage, for example, is small, are much more vulnerable than markets in which you have a clearer and stronger foothold. The economist analyzes these features and views an undertaking which has to earn its dollars by such intensive marginal efforts as more vulnerable to the impact of changing economic conditions than one which resorted only to trying to get the more reliable portion of the business and which in fact could make the necessary rate of return by only taking the more reliable portion of the business.

That distinction carries through public utilities, in my opinion, very clearly. It s not an uncommon position to take at all to say that a given electric company has a substantial proportion of industrial business, therefore look out for it. It does not have the balance and the certainty of one which confines its efforts largely to the more reliable domestic business, for example. (Motion to strike above answer by Commission Counsel denied.)

A manufactured gas business, for example, which is in a position to earn a satisfactory return from a back log of the manufactured gas business in the range use of gas in the home, in my opinion reflects one type and degree of hazard and economic risk; but if a gas company goes out, for example, and assumes to sell gas for house heating purposes, the income which it obtains from that additional business is an income which must be appraised in an entirely different way than the income earned from the solid and reliable domestic range business.

To revert once more to the electric industry, when the electric industry goes into the range business and starts getting out on its thin ice, so to speak, or in the hot water heating business, it similarly receives from a class of business income which must be valued on a different basis than the income from its most reliable sources.

It has been my opinion for a great many years that a refinement of income valuation is called for on the basis of the character of the business that an enterprise does; and it is no extreme and undue refinement, in my opinion, to recognize such readily distinguishable classes of business as domestic and industrial, and even to divide domestic business into that part of the business which a given type of company has a clear control over and a hold on from those in which it is distinctly in the competitive area. (Motion to strike by Commission Counsel renewed and denied.)

I have elaborated the answer to the question as to whether, in my opinion, there is any recognition to be given from the standpoint of hazard and risk to the fact that a company has to operate at a high load factor and that it has to go and get additional classes of business to operate at a high enough intensity to make the income which it is making.

I have been using "load factor" in the discussion probably as synonymous with "utilization factor." Load factor more narrowly should probably be defined as the ratio of the average demand to the maximum. I was here using utilization factor really more accurately, namely, the ratio
of the average utilization to the plant capacity, which
1168 may be a little different from the peak which it
reaches. (Motion to strike by Commision Counsel
overruled.) The income obtainable from industrial sales is not as reliable and not as certain and not as dependable, and therefore would not be capitalized at the same rate as the income from the more reliable, certain and dependable domestic service.

Cross-Examination Interposed by Mr. Slaff.

There are a number of small manufactured gas companies which probably have an insignificant amount of industrial or even commercial business. Larger gas companies attempt to obtain such business if they can obtain it at compensatory rates. That illustrates perfectly the point that I am trying to make, that when you have a gas company that goes out and gets some additional income from that kind of a source, it is not appropriately viewed as having the same value as income obtainable from other sources. The fact that they do it and try to get what income they can has not necessarily anything to do with it. I think substantially all manufactured gas companies secure some revenue from other than domestic purposes. I have in mind one company—a little gas company at Marshfield, Wisconsin that has no industrial gas business.

I have not had occasion to examine page 2 of Mr. Gilman's exhibit. I do not know his testimony other than the industrial section which I looked at after he gave it. I have not had occasion to look at that exhibit.

Direct Examination by Mr. Morgan Resumed.

I did not mean to imply that there was anything inappropriate about trying to go out and get industrial load or any kind of load which was incrementally compensatory.

I was simply making the basic observation, which is absolutely valid in my understanding of economics, that the source and character of the income is a factor to be considered in the rate at which it is to be capitalized, and that income derived from the more hazardous sources is properly classed in the higher rate than income from safe and secure sources.

Obviously an investor would be impressed with any demonstrated experience such as the falling off of revenues, mostly from industrial load, as between the years 1937 and 1938, of more than three-quarters of a million dollars; but a really qualified analyst would go further than demonstrated experience and attempt to calculate what the probable experiences of an enterprise of a given type of market and engaged in a given type of service would be. I would not consider it adequate to rely merely on the experience of a relatively short period of time. The fluctuations on account of the economic cycle is only one of the factors which would be involved. A business, for example, which falls within the segment of competitive business for alternative uses is subject to decline due to factors other than those arising out of the business cycle. But, a slight change in the technology or the efficiency of appliances for utilization could upset a delicate balance in the competitive area and throw you out of that particular field.

Summing up all of the elements that I have discussed here, it seems to me to be the reasonable economic expectation that higher unit costs of production would result in the future, and that is a circumstance that an investor would consider.

1169 I am not basing that statement upon the assumption that there will be rising prices in the future. I made no assumptions with respect to rising prices at all. I was not relying upon any forecast as to the probability of price behavior. The analysis I made is valid irrespective of a changing price level. That is an entirely different factor. The possibility of rising prices has been a threat for some years now. In my opinion we have engaged in various public and private economic practices which have laid the basis for a tremendous possible rise in prices.

I meant to discuss the probability of rising prices. "Possibility" is always present irrespective of the conditions with respect to a phenomenon such as changing price levels. A great many economic factors have developed in the last six or seven years making for a great probability of a rising price level. That probability of a rising price level has been recognized pretty generally. A tremendous rise in prices has not as yet occurred, and in my opinion probably will wait upon the development of one additional factor. We know that the full utilization of one or the other of the factors of production is probably necessary as a requisite to a rise in the price level. Even though prices seem merely to go up, actually there must be changes in the relationship of the supply and demand before prices are affected. The demand may well be affected by the threat of the supply of money, a threat of inflation or that sort of thing. I did not mean to get involved in all of the factors which might be back of a change in the supply or demand. I simply meant to point out that prices do not just rise. There must be changes in human opinion and willingness to buy and sell. One of the requisites of the development of that kind of a condition is the pressure upon the available supply of some one or more of the major factors of production, and that seems to have been what is primarily lacking during the last seven years.

The outbreak of the War, for instance, furnishes possibly the final remaining circumstances needed to bring the process to fruition for which we have well set the stage, namely such utilization of our industrial production capacity, such demand upon resources as require producing those products which can only be provided at higher costs, and which will bring us to the point where we will actually experience this rise in prices which a great many economists have considered probable for a number of years already.

I consider one of the most important differentiating characteristics between these enterprises and the public utility gas companies to be the lack of the control over the market; and I use the word "control" in a general sense. The fact that the production and transmission company dos not actually exercise what I think of as the business control over its market is an adverse factor. The inability to deal with the ultimate market in a manner which is most advantageous to the production and transportation company puts limitations on what it could do either to work this out to its own best advantage or in case things are going bad, to protect itself as effectively as it might be protected.

I think the situation is clearly comparable to that of a manufacturer who finds that his outlets, his contact with the ultimate consumer, is only through the buffer of a distributor or a limited group of distributors. What they do determines how effective he can be; and the tendency has been in large scale business in this country to try to break through that buffer in order that the producer who is vitally interested in the volume of distribution may actually conduct his business affairs in such a way as to achieve the optimum result.

1170 *Cross-Examination Interposed by Mr. Booth.*

I said I used the word "control" in the business sense. That the producer did not have the discretionary power to control the manner in which the market would be exploited, to determine the shape of the rate curve, to determine to what extent he would engage in the exploitation of a given class of business. Suppose he is of the opinion that the house-heating business could be very well developed in a given market; that in his opinion it would pay to spend a considerable sum of money to develop the househeating business, but those in the control of the market may not think so, and consequently do not put themselves out to develop that particular part of the market. What I meant by lack of control is that a producer is not in a position to force the enterprise in control of the market to go out and develop the market as the producer would like to have it developed.

Direct Examination by Mr. Morgan Resumed.

In my opinion an investor in the securities of defendants would be impressed and should be impressed with the possibility of direct competition by a raiding line, as that term is commonly used, or the discovery of a different source of supply at a shorter distance from the City of Chicago than the Panhandle of Texas. Direct competition would apparently result in either forcing lower prices for the product of the existing facility, or a dividing up of the market possibly; and a division of the market and its effect on the industrial and internal economy of such an enterprise would mean a lower utilization of its facilities, a lower revenue volume, without proportionate reduction in costs, and consequently a lower income. Apparently there are one or two cases already of proposals for building competitive natural gas pipelines in the United States who are attempting to obtain or have actually obtained approval of the Federal Power Commission for the building of such competitive lines. As I understand it, there is one of which there has been approval, the case in which Commissioner Manly dissented, and another case is under consideration where an application has been filed with the Commission.

A threat of direct competition in an industry in which the capital is so specialized and so long-lived and so immobile as in this kind of an industry is viewed as particularly hazardous.

Another factor which must be taken into account is the competition in which natural gas finds itself with such fuels as fuel oil, distillate, coal, and things of that sort. This is certainly true of a company like defendants, 40 per cent of whose volume of gas is sold for industrial purposes. Any change in the relative position of competitive service or competitive fuels ought to be taken into consideration. Any change in the relative position of such competitive fuels would have the same general effect that the introduction of a directly competitive line would have; and that is that a loss of any substantial portion of the business due to the relatively more favorable price of oil or coal would reduce the volume, which is very significant for this particular enterprise.

1171 *In my opinion there is a distinct threat in the aggressive market policies and practices of the electric industry. I have testified before with respect to the future of the gas industry that I consider it distinctly prejudiced by the apparently increasing success of the electric industry in capturing additional portions of its markets. The policies and practices of the electric companies are becoming more of a threat all the time under the pressures under which they are operating in the United States. The pressure, for example, to show a large volume of consumption per customer leads them to seek business which may have a very small margin of profit in it, such as the electric range or the electric water heater, but which builds up the consumption per customer. This also has some direct economic advantage since it puts the customer at a lower point in the rate schedule and thus makes him available for the buying of other services at lower prices in the rate schedule.

The pressure on the part of government to force domestic rates down and to achieve lower average rates in the electric industry, is, in my opinion, prejudicial to the gas industry because it puts an added pressure on the electric companies to seek to invade the common ground between the two services and take a larger proportion of it. In general I am of the opinion that the management of electric companies is more aggressive with respect to fighting for the common market than are the gas companies. I cannot particularize, but this is the general observation for which I have been on record for a great many years. I have made further studies as to the factors that necessarily enter into the arrival at a proper rate of return, that is, the factors that I saw constitute hazards and risks confronting these companies. I believe in building a solid foundation of the most fundamental factors and working from those to the more immediately and directly observable applicable evidences. (Motion by Commission counsel to strike overruled.)

After carefully considering all the fundamental factors, I moved to consider the objective form in which these factors expressed themselves. I studied the market behavior of investment opportunities in general; I have studied the market behavior of investment opportunities in public utility industries; I have studied the market behavior of investment opportunities in the natural gas business; I have informed myself as to the character and conditions and circumstances under which the natural gas industry has been able to bargain for its capital supply.

In connection with my academic work as well as my consulting work I am professionally under obligation to keep informed about the general behavior of the financial markets and the earnings of business in general, as well as those particular lines of endeavor which happen to be represented by those consulting me. I take every occasion and opportunity to do that.

I have examined pages 6 to 15, inclusive, of Exhibit 150, and I believe I understand the character and import of the facts offered there. (Objection by Commission counsel overruled.) I would consider an exhibit of this sort of fundamental value in establishing something of the metes and bounds or in staking out the limits, so to speak, of the earning power of industrial capital. I would not be impressed by the results of any particular classification; neither would I consider that the result of a summation of

this sort necessarily posits a point that is the proper rate of return for the natural gas industry or a particular company in the natural gas industry; but I think it serves a useful purpose. In fact, the device is rather commonly employed for orienting the approach, for giving perspective, and for setting some of the limitations within which judgment would tend to find expression. Without anything of this sort one would be relatively helpless as to any understanding of what the limits really are in industrial enterprise. I have attempted to make an
1172 appraisal of that evidence as I would appraise it.

Having access to pages 6 to 15 I looked it over carefully and have some opinions about its possible validity and the extent of its possibly appropriate employment. I made a few checks on the fundamental statistical validity of such an array. (Objection by Commission counsel overruled.)

I noticed in viewing this array of average returns on invested capital for the period 1934 to 1937, that the array reflected a very considerable extreme of items running from .57% up to 37.69%. Any statistical array which affords that kind of an extreme is always worth critical appraisal to determine whether or not an averaging of that kind of an array is an appropriate treatment. My own approach to testing such an array would be to determine the representativeness of various levels. Consequently, within the limited time and energy at my disposal recently, I just arrayed these rates of return from the lowest to the highest in an effort to see whether or not there was any distinguishable mode or representative level which might be more valid and which might either support or cast some doubt on a simple mathematical average.

In the first step of determining a mode on a 2-point interval no clear mode is indicated. In the second step of determining a mode on a 4-point interval no single mode is indicated, but 10 items and 9 items, respectively, fall within two adjacent groups, giving us an adjacent grouping of 19 out of the total number of items available. That range is from 6.16% to and including 13.98%. That seems to be the dominant group within the array. Just to deal with keeping an even number of items on each side, because 13.98 appears twice, I have taken the central 17 items of this array, which leaves 10 on either extreme and is more representative possibly. In other words, excluding the extremes on both ends, a very common statistical testing device, I found that a simple average of a more homogeneous segment works out at something over 10% in the average, which is fairly close to the 11.04% obtained by taking the series as a whole.

The second point of appraisal appropriately made of such an exhibit, I think, is with respect to the period 1934 to 1937. I do not consider the period 1934 to 1937 representative of the full earning power of industrial capital in general. It is a matter of common knowledge that the industrial earnings in the period 1934 to 1937 were relatively low and unsatisfactory to business.

Cross-Examination Interposed by Mr. Slaff.

It is understood that we have been in a depression during this period, and if depression means anything, it means a low level of industrial earnings and industrial activity. The output of the industries, the profits of the industries, the employment of labor, all bear evidence to the economic conditions maintaining since 1930, and the period of 1934 to 1937 still includes too large a proportion of the years in which those unsatisfactory economic conditions prevailed to reflect representative earning power. It is pretty difficult to estimate whether this four-year period would be representative of the decade from 1930 down to the present. 1938 is not in there, and 1939 is not in either, which were years which represented some considerable improvement, in many lines at least. If this could have been extended to 1938 and 1939 I believe that the ratio shown here would be higher than it is with including merely 1934 to 1937. I do not think it is representative of the nine or ten years from
1173 1930 through 1939. This decade is not comparable
to the period 1923 to 1933. (Motion to strike above testimony by Commission Counsel denied.)

By the term "normal" I meant it in no other sense than it is commonly employed in the literature of prosperity and depression. Our references are always, of course, to some past period. We do not think of normalcy with respect to the future. It refers to what has been a representative expected earning power in the past within the memory of the people who are now evaluating the present and looking into the future. Thus, with respect to indices of price levels or with respect to purchasing power and that sort of thing, it is common always to look back. In the Bureau of Labor Statistics, indices are based on 1926 in the name of normalcy. This is not a term of such definite and specific meaning that it would apply to earnings experienced in any particular period of the world's history.

I am using it in the same sense in which it is ordinarily used, and I appreciate that that is the way the term "normal" is used. We are prone in this period to think of much that happened to us from the late war to 1930 as normal. That would give you one norm. Then you could go back and speak in terms of a 20-year period, and you would have a longer normal period. I meant essentially the pre-depression experience. And for a larger period than the past-war pre-depression decade of say, 12 years. And for our earlier comparison the four years here are not normal, as they reflect the continued depression period from 1930 through 1939.

Direct Examination by Mr. Morgan Resumed.

I would like clearly to go on record that thoretically the use of an investment base is for rate of return determinations invalid in that an investment figure is by definition always a past figure, and the valuations which are of final importance in this kind of an undertaking are present value figures. I have testified to that on other occasions, and I believe that is the correct way to do it. That would certainly be a disqualifying fact if we were concerned here with one company. If this were one company and without any indication as to when it had made its investment, and under what conception of accounting records it had recorded this investment, and on what principles it was continuing to place certain reliance on past figures drawn from books of account, for any one company that would invalidate any comparison with the past. But it is to be noted here that we have not one company or just a number of companies, but what purports to be a cross-section of American industry. Consequently, it should be observed that what is known as the year of inception of American industry is not some one year, but that the date of inception of a cross section of American industry undoubtedly spreads itself over the period of development of American history; so we get a synthesis of all sorts of different periods, high periods and low periods, of original investment which are undoubtedly reflected in the investment figures carried by this cross section of American industry; in some of the last ten years there was relatively large investment reflected in those figures. There would not relatively be as much investment in the last ten years as during the higher priced periods which preceded it.

1174 The year of inception would be spread over all price level history, including not only the highs and the lows, but the years of expansion, so that the incremental investment of these enterprises may safely be presumed to be spread over such a substantial period and vary sufficiently to substantially negative the probability that this investment reflected here was all at the bottom of the pit or at the top. In fact, the behavior of investment figures and cost new figures with respect to many industries appeared to come to a kind of stalemate about 1931. That is, the public utilities—electric companies in particular—which were fairly early in the history and which developed in growing communities, found that by 1931 the question as to whether investment cost or present cost was used became almost a matter of indifference. That is, a coincidence appeared to be developing at that time which was something of a consideration in connection with rate matters and others.

(At this point preliminary cross-examination by Mr. Booth of the witness to determine the competency of the witness' statement) "That the question of whether investment values are on the average still high, I think could be resolved to a fairly safe estimate that yield on the present value of the investment of these enterprises would show a higher percentage." (The following testimony appeared: The witness also stated that he had not studied the cost records and investment value of any particular company but that he had studied the cost records and investment value of many companies; that he is acquainted with the volume of those right-downs and the industries in which they have occurred and that he has a basis of comparing the extent of right-ups and right-downs in industrial businesses with the extent of such right-ups and right-downs in the public utility business; that he had spent two years studying in particular the capital revaluations of public utilities.)

Preliminary Cross-Examination by Mr. Booth.

On page 6 of Exhibit 150 the first classification of corporations is Automobile Parts and Accessory Manufacturers and that is composed of 40 corporations shown on page 7. The name of the first corporation is Ainsworth Manufacturing Corporation. I don't know where its business is located. I have never seen its property. I do not know what its property consists of. I do not know what buildings comprise the Ainsworth Manufacturing Corporation. Nor do I know the present condition of its property.

The next one is the Aluminum Industries, Inc. I don't know where its business is located; I have never seen its property; I have never made a valuation of its property; I have never talked to anybody that has made such a valuation; nor have I ever talked to anyone who talked to anyone else who has made a valuation of its property. (Objection by counsel for the company.)

I do not know the total capital investment in the Aluminum Industries, Inc. nor do I know when the investment in that corporation was made.

The next company, the Backstay Welt Company, is another company with which I am not familiar with its property. I do not know where its property is located; what its properties consist of; what the total capitalization of that company is; when the capital was invested; nor do I know the present condition of its property.

My answers would be the same with respect to each and every one of these corporations on pages 7 to 15 of Exhibit 150, with the exception that I cannot say that there are not some that I may not have examined. (On motion by counsel for the two commissions, the sentence first above was stricken.)

(At this point counsel handed the Examiner a document entitled "Natural Gas Pipeline Company and Texoma Natural Gas Company Data Concerning Rate of Return—Witness H. B. Dorau" with the request that it be marked for identification. At the Examiner's direction the document was marked Exhibit 152 for identification.)

Exhibit 152 was compiled and prepared by myself or by my assistants under my direction. The chart on page 1 reflects the changing yield to maturity at market prices of Moody's 40 Public Utility Bonds, which are divided into four series of ten selected bonds each by rating classification. This chart is composed of yields reported by Moody's Statistical Service for the Aaa, Aa, A, and Baa classifications. It should be understood that each of these series includes at each time ten bonds. It should also be understood that Moody's chooses to change the content of the series from time to time as they feel it necessary to maintain comparability or because securities drop out. In this chart the vertical axis measures the yield to maturity at the market price in per cent per annum. The horizontal axis expresses the years by months in the period 1919 to 1939.

The legends Aaa, Aa, A, and Baa are the identifications which Moody has developed to indicate its highest grade bonds, its second highest grade bonds, and its third and fourth grade bonds. The Aaa bonds are the highest grade of bonds.

In my opinion a chart of this sort affords a background for an understanding of the changing yields of selected public utilty bonds. Thus it affords a basis for comparison, a point of departure, so to speak, for coming to a conclusion as to the relative position of securities of natural gas companies.

I would like to observe that this is the kind of chart which is often used as a point of departure in a study of necessary supply price of capital and that I employ it only as such a point of departure. I do not mean inappropriately to propose to rely on this to reflect the necessary rate of return as such, because a chart of this sort does not give the full range of risk classifications, and of course, as is obvious from the title, this is a chart of public utility bonds. Obviously the risk element in the preferred stocks or common stocks are not intended to be reflected.

1175 *Cross-Examination Interposed by Mr. Booth.*

By the term "point of departure" I mean a beginning point, a starting point. I do not mean a leaving point. This is the beginning and not the end. This is the taking-off place from which we start.

Direct Examination by Mr. Morgan Resumed.

The curves in that chart give a background picture of the changing levels of the yield return on the four different classifications of securities of different risk characteristics. It is readily noted that the levels of yields of securities of these classifications have changed markedly from period to period. There is the post-war rise in 1920 and 1921, followed by a period of declining yields on all classes, reaching a low point in 1928, followed by a gradual rise to 1931 and a marked rise in the security classes representing the larger degree of risk through the years 1932 and 1933, after which the returns declined again to the levels indicated at the last point about the middle of 1939. It is significant that the two higher classes of bonds seem to show less reaction to certain temporary conditions than the other two classes, particularly in the periods 1920 and 1921, and 1931, 1932, and 1933, and about the first of 1938. That is a characteristic of the behavior of the yields on these classes of bonds of different risk characteristics which is worthy of note. I attempted to direct particular attention to that aspect on the revision of the chart at page 5.

The figures shown on pages 2, 3, and 4 are merely the supporting data which is incorporated in the chart on page 1.

Passing on to the chart on page 5, it will be readily observed that that chart is the same as the one on page 1 with the addition of a fifth curve. This fifth curve, which is found in the dotted line and running generally toward the bottom of the chart, measures the difference at each point between the yields on the Aaa bonds, the highest grade, and the Baa bonds, the lowest grade shown. This I consider significant because we are dealing here with four classes of bonds of different risk characteristics; and the changing amount of risk differential which develops throughout a period such as is recorded from 1919 to 1939 I believe is significant.

It will be noted that the difference between the yields of the Aaa and the Baa bonds rises during the period of uncertainty in 1920 and 1921 and declines to a low point, in 1928, then rises substantially to 1931 and sharply through 1932 and 1933 as the level of bond yields rose during that period. Since 1933 the difference in yields between the class of highest risk and the class of lowest risk declined to a fairly low level; and this occurred again in 1936, from which, however, it jumped up rather quickly to a fairly high level in the early part of 1938. In fact, in the early part of 1938 it reached a higher level than at any time in the series except for the middle of the depression period of 1932 and 1933. Since the forepart of 1938 that differential index has again declined to a point which is still higher than the low point reached in 1936, and it is interesting, and I believe significant, that the differential in 1938 remained higher than it was throughout the period, say 1924 well into 1930.

1176 I think the changing differentials here are clearly indicative of the greater sensitivity of the series representing the higher risk securities to the uncertainties and the fact that those differentials still maintain the relatively high levels compared to the period of which we choose to think as the normal prosperity of the Twenties. The figures on page 6 support the differential curve which was added to chart 5.

The chart on page 7 represents another variation of the chart on page 1. With the exception of the fifth curve at the bottom it is identical with the chart on page 1, except that in comparing here the absolute difference between the yield on the securities of the highest grade and of the Baa grade it seemed only appropriate to determine what the relative significance of that difference was. I was perfectly aware that the absolute difference would fluctuate merely by virtue of the changing level itself, namely, the mere magnitude of the numbers here contained would result in an increase in the absolute differential as the level of the four curves moved up from 4% to 6% or higher. It seemed only appropriate that we make a determination as to whether the relative significance of the differential changed in harmony with the absolute change; in other words, whether the absolute change was more or less than proportionate to the level at which these securities were selling.

The curve labeled "Ratio Baa to Aaa" at the bottom of page 7 is a recording of that ratio. The method of determination of the ratio is simply to impose the yield at each point of the Baa classification over the yield of the bonds on the Aaa classification and determine the ratio. Thus, when it reaches a level of 2, it is two times as much. This curve shows a different character than the absolute difference curve in that in the period 1920-

to 1921, when we had a fairly substantial rise in the absolute difference, there is now no great rise in relative difference, indicating that the rise at that time in the absolute difference was probably only proportionate to that rise in the level of yields itself, thus disclosing what I consider one of the limitations on an absolute difference measure as an index of this circumstance.

Thus the curve holds fairly steady all the way down through 1929, begins to rise at the end of 1930, and then indicates that the increase in the absolute difference was more than proportionate to the rise in the level of the bond yields as a group. Some recovery took place following 1933, through 1934, and the new low point was reached in 1936; that is a low following the depression years of 1932 and 1933, with a rise in 1937 and some recovery in 1938. But it is interesting now to use this relative measure of the risk differential to note that even though there was a recovery following the years 1932 and 1933, and even though there was some recovery following the rise of 1937 and the forepart of 1938, that the level at which this differential holds since the depression continues to be well above the level which it held before the year 1932. In other words, the relative significance of the risk differentials since 1932 and 1933 has not declined to the levels prevailing during the period 1919 to 1931.

I interpret this as evidence that investors are placing a relatively higher significance on the risk differentials that exist than they did during the period 1919 to 1931.

1177 There is a great deal more that can be said in the interpretation of a chart of this sort. I would like to make it perfectly clear that this curve is the ratio curve, and that any ratio curve is of course influenced by both of the factors used to develop a ratio. Thus, the behavior of both the Aaa bonds and the Baa bonds enter to influence the ratio result. It can be looked at either way, that the Baa bonds have done it or that the behavior of the Aaa bonds have made the ratio what it is. I think that is perfectly clear to anyone who understands the ratio relationship.

If we wanted to carry this analysis further, we could measure that differential as between every one of the classes and the Aa bonds, for example. From observation, it probably can be seen that in general a similar result, although not as magnified of course, would be portrayable.

It simply means that if it were disclosed by such a refinement that the relative differences were maintaining a similarly or proportionately high level that the valuation of the the risk between A and Aa or between A and Aaa would represent a relatively larger consideration in the investor's appraisal of those securities at that time than it did at the earlier period with which we are comparing it.

The figures on page 8 represent the ratios of Baa to the Aaa.

The chart on page 9 is but the superimposition of the preceding curves of the absolute difference and ratio difference on one chart to facilitate ready comparison of the behavior of an absolute difference curve and a relative difference curve. It is merely a combination of the other three charts. And for visual purposes, this makes it easier for anyone to compare the behavior of the absolute difference and that of the relative difference. It shows that the relative importance of the differential yields does not fluctuate as widely as the absolute difference, thus indicating the effect, in my opinion, of eliminating the influence of mere magnitude of numbers on such a measuring device.

Passing on to the next chart, appearing on page 10, the vertical scale is again the yield percent to maturity as before, but the horizontal scale is only intended to indicate year-end points for this purpose instead of the monthly points as in the more elaborate preceding charts. Thus, the prices and yields for the securities developed on page 10 are based upon year-end or nearest to year-end prices. The reason for doing that was simply a reduction of the tremendous amount of labor involved in the calculations of this sort; and I think for purposes intended by this chart, a single point is probably adequate. I took the year-end or nearest to the year-end, probably never going out of the month of December or the nearest price available in the year.

It is a pretty well understood fact that the Moody Series which I used in the preceding charts and which are so commonly used as a point of departure or beginning, represents a highly selected bond series group. The 1178 standards of selection are fairly rigorous, I understand, and I rather doubt whether they are representative of the levels at which securities of these classes in general are sold; so in order to take a step in the direction of greater reality and representativeness, a number of series were developed here just to see how far we would depart from the traditional levels which are so often referred to.

The first series on chart 10 reflect the yield at the year-end or the last available price of 55 gas and electric company bonds. I might say that one additional feature employed in this chart is the effort to maintain continuity of the bond in a series, actually to attempt to keep the same group together and see what happens to it. Some analysts have some doubt about the changing content of a series like Moody's series, so a great effort was made to obtain a continuous series. A great effort was also made to develop as large a continuous series as was possible; and I want to say that that involved a matter of great difficulty in that bonds have a habit of inappropriately dropping out and disappearing and spoiling a series, making necessary recalculation backwards to maintain a uniform base.

The heavy solid line represents therefore the yields as indicated for 55 identical gas and electric company bonds. These are shown on pages 15, 16 and 17.

The heavy dashed line represents the bonds of 18 manufactured gas companies, and the same identical bonds throughout the series. The light solid line represents the changing yield on 24 public utility preferred stocks; and the light dashed line represents 22 of those 24 public utility preferred stocks. The reason for encumbering the chart with that fourth curve was because two of those preferred stocks that were in the 24 so dominate the picture that it seemed only good and fair statistical procedure to show what the curve would be like with those two eliminated. I probably failed to mention that these are weighted average curves; and that is why the 22 and 24 stocks series are developed, because of the weight of the two preferred stocks in size so dominating the picture. The two preferred stocks referred to are those of the Pacific Gas and Electric 6 percent cumulative 1st preferred, and the Consolidated Gas $5 cumulative. They were in volume so large that we wanted to be sure that the character of the curve was not the character of those two preferred stocks.

The fifth line is introduced again for the purpose of base comparison. To depart from the exclusive use of Moody's series, I took recourse to the Standard Statistics Index of Yields on their highest grade bonds, and recorded that at the bottom of the chart to establish something of a point of reference, a base line from which to judge the comparative level of these indices, representing different classes and different risk characteristics. I don't know how many bonds are represented in the Standard Statistics group. The Standard Statistics does not publish the content of their A-1 plus series and refuse to take on the task of giving it. I want to say for the record that I tried to get it. I have tried before and failed before. I would like to say this about it, however, for your information, that it is a larger series than Moody's 10 Aaa. They are willing to say that they include a large number of bonds falling into that classification, but they won't tell us how many or which ones.

1179 *Cross-Examination Interposed by Mr. Slaff.*

This is all the same series. It is not weighted. In case you are confused on it, I will have to make the record clearer on it. Their series is not weighted, and it is the same identical series. There is not much point of weighting in that, because it represents a large number of bonds, and the probability of any one series or bonds overweighting the thing is remote. I think the difference in the curve on page 10 and that on page 11 is due to a shift in the plotting.

Direct Examination by Mr. Morgan Resumed.

Still referring to the chart shown on page 10, I do not know whether I stated that the purpose of this chart was to establish the levels of public utility security yields when identical securities are maintained in a series throughout a perod of time. The purpose is to establish a more representative level of security yields than is obtained from the charts which reflect the changing yield of a selected series, such as the Moody series, and to determine the relative position of gas company securities by the use of a manufactured gas index, because so few gas company bonds ever find their way into the series that are commonly used. Thus the Moody's series of 40 public utility bonds has only a few manufactured gas company bonds in it; and even that series of 40 is largely influenced by electric companies, composite gas and electric companies and telephone companies. So the third purpose of this approach is to see how manufactured gas companies place in a range of this sort. Then, in the fourth place, it is to get some picture of the levels for preferred stock yields as evidence of the price of capital for a grade and level of security different than bonds, one that is nearer to the greatest risk margin of the whole capital structure.

The chart on page 10 is that kind of a chart. Now I think I should like to add, for clarification purposes, that the average yield of Standard Statistics A-1 plus bonds that is used here is the average as Standard Statistics published it—that is not a weighted average and ought to be worded that way; and I think we were a little bit derelict in not clarifying it, but I thought people rather knew what the Standard Statistics Index was. The Standard Statistics Index of A-1 plus bonds on chart 10 is an index based on December 20th prices, which unfortunately I did not see fit to record in a table, but which I would be glad to furnish if there is any interest in the December 20th prices as such.

The chart on page 10 shows markedly different levels of security yields for these larger and more diversified groups. The difference, for example, between the Standard Statistics Index of bond yields on A-1 plus bonds is marked throughout the period ranging from approximately 1½ to 3 percent in amount. It is particularly to be noted that the difference between the Standard Statistics Index of yields on A-1 plus bonds is generally becoming greater. There is a fairly reasonable and close approximation in 1930, with wider differences in 1932, 1933, and 1934, some recovering and narrowing of the difference in 1935 and 1936, but an increasing disparity apparent again in 1937 and 1938. Now, with respect to the 18 manufactured gas company bonds, they hold a relatively favorable position in the public utility index down to 1934, after which they seem to fall into a certain amount of disfavor, crossing both the curves for the 55 gas-electric company bonds and the average yield on 24 public utility stocks. The peculiar behavior of that series I analyze in more detail in connection with the chart on page 11.

1180 The figures on page 12 support both the charts on pages 10 and 11 respectively. The supporting figures are all there except those underlying the Standard Statistics monthly data, which I have already explained. These appear on page 18.

The yields on the 24 public utility preferred stocks rose from a level of about 5.43 percent in 1930 to 8.39 percent in 1933, declined to a low yield of 5.08 in 1936, and rose to yield 6.24 at the end of 1937, and 5.65 at the end of 1938, reflecting a considerable disparity between the yield level of this risk security as compared with the bond yield levels.

I think I indicated earlier in the discussion that included in the series of 24 public utility preferred stocks there are two overwhelmingly large issues of high grade preferred selling at very low yields. In order to note the effect of the exclusion of these two dominant preferred stocks in a weighted average, the same calculations were made for the remaining 22 preferred stocks, and charted as a light dash line. The remaining 22 preferred stocks were available at an average yield of 5.84 at the end of 1930, rose to yield 10.98 for 1933, declined to a low of 5.59 in 1936, but rose again to yield 6.8 at the end of 1938. Viewing the resulting picture as a whole, it is clearly indicated that from this more representative picture of 97 public utility securities over the perod 1930 to 1939 the yield has been distinctly on the upper side of 6 percent.

I am addressing myself to the chart on page 11. Statistically it is always a question whether a simple average or a weighted average should be employed. Actually no categorical answer can be given. It depends on the character of the data and to some extent on what is desired to be shown. Thus, for example, in connection with new financing, the volume of new financing can be reflected as an average yield per issue or an average yield per dollar of capital raised. Now, if attention is to be directed to the dollar of capital that was raised, the appropriate thing is to weight the issue by its size and get a figure that is the average yield per dollar of capital; whereas, if you are interested in the representative level of security issues as such, the simple average would be the appropriate one to employ. In general, the important thing is to understand what is being obtained. Actually, there is probably never such a thing as a weighted average. A weighted average immediately becomes an average of something else, that is, it is an average per dollar instead of an average per issue, that is all.

Thus, the transposition from simple to weighted average, or the reverse, should be carefully made. In order to avoid any question of the sort, as to which is more appropriately employed where there seems to be some argument on either side, I have represented some of the figures which support the chart on page 10 in the chart on page 11, on a simple average basis. In this chart the same 55 gas and electric company bonds are employed to develop a simple yield index based upon prices in December of each year. These 55 gas and electric company bonds were available at a simple yield of 5.18 at the end of 1930. The yield on this identical list of bonds rose to 7.60 at the end of 1933, declined to a yield of 4.19 in 1936, and returned to yield 4.48 in the end of 1938. So that that series, I believe speaking from memory, runs a bit lower than the weighted series, indicating that the effect of sheer volume was in the direction of those which yielded a slightly higher yield.

1181 The index for manufactured gas company bonds is broken into two series here in order to more clearly display the true facts with respect to these securities, one including the same 18 bonds used in the chart on page 10, and one using only 14 bonds. It was discovered that during the last two years of the series two of the continuously employed bonds were starting to act up very unsatisfactorily, declining in price which resulted in abnormally high yields; so in order to eliminate the effect of the two that were distinctly non-representative from the rest of the series, those two were eliminated. In order not to cause too great a distortion on account of that, the two lowest bonds for simple average purposes were also eliminated. In other words, the series of 14 is a selection of 14 from the middle of the 18, to avoid the effect of the extremes and get a more representative behavior.

I can not determine from that page which were the two highest and which were the two lowest. My memory is that the two highest ones eliminated were the bonds of the Laclede Gas Light Company. I do not recall which the two low ones were, but the two highest and two lowest were eliminated. Relative volume has no influence here. It is a simple average.

It can be noticed here, as the result of that purification in effect, as to that statistical series, that both series plotted in the dash lines follow very closely together, display a fair degree of homogeneity, until the end of 1938 when a marked disparity between the two series develops; and it is the suggestion that the seeking for a more homogeneous sample is the justifiable statistical procedure. I believe that the index of the 14 bonds is consequently, over the whole period, more representative, but there is not any violent difference until we get into 1938.

Now, it will be noted again on the simple average basis both the 18 and the 14 manufactured gas bond series held below the average yield on the 55 gas and electric company bonds down to the end of 1934, at which time, as we noted in the weighted average yield analysis, they seem to have fallen into increasing disfavor and were available at distinctly higher yields than gas and electric company bonds.

The index of 24 gas and electric company preferred stocks on a simple average basis, now freed from the influence of the generally lower yields on the large issues of large companies holds at somewhat higher levels than the weighted average as reflected on the chart on page 10, holds a somewhat higher level than does the same curve on a weighted average basis. The yield on the series never falls far below 6 percent on a simple average basis reaches its high at substantially 12 percent at the end of 1933, declines to 9.93 percent at the end of 1934, and to 6.04 at the end of 1936, to rise again to yield an average of 8.10 at the end of 1937 and 7.10 at the end of 1938.

I think, from all of the trends indicated up to this point, it is rather clearly indicated that there have been, in the period since 1930, such marked fluctuations in the yields on securities that to have taken any one particular point there and said that that is representative would soon
1182 have proved you wrong in either direction and in
both directions at one time or another. Consequently, I think, from an evaluation standpoint, some perspective in terms of where these levels do come from and how they have changed, is useful, and is something of a discipline to jumping at conclusions with respect to the level at which they happened to be at any particular moment.

The index of manufactured gas company bond yields has probably more in common with the natural gas position than any other group of bonds so far analyzed and traced. The degree of protection afforded bonds of a series of this character in terms of times interest coverage is, in my opinion, needed to throw light on the significance of these relative yields.

In my opinion yields studied independently of coverage and yield levels without reference to the protective income available for the securities in any bond included in such a series, are relatively meaningless for a definitive and final judgment. Thus any bond series, for example, may be showing a declining yield on account of the improved position of the constituent bonds; not that bond yields are going down, but that the yield on a given series whose quality is improving may be a factor in causing it to decline.

The simple yield on these 18 manufactured gas company bonds as of March, 1939, was 5.51 percent. Now I have computed the coverage on that series of bonds just to give illustration to the point which I tried to make. The simple yield of 5.51 percent on 18 manufactured gas company bonds showed requirements earned of about 3.74 times. That means that these bonds, the prior obligations, had their requirements covered 3.74 times, on the average.

That was in March, 1939. I hasten to add also that the March, 1939 ratios are calculated by reference to 1938 income. I believe I heard a witness here earlier adopt the same technique, and I think it is an appropriate one to use.

In connection with bonds I do not think it is necessary to make the complicated adjustment, because bondholders look at the annual report of the past year more than stockholders, trying to anticipate the future. So I have done it on a simpler basis, simply using prices as of March, 1939 against 1938 reported income.

For the purpose of establishing some basis of appraising these average yields in terms of coverage it may be noted what the average coverage on the middle six items in Moody's average of Aa bonds was for the year 1938. Now the reason for taking the middle six is again the statistical reason for avoiding the influence of an occasionally unusual ratio which might be two or three times as high as some low one and completely distort the picture.

Taking the six middle items of Moody's Aa bonds for the year 1938, the coverage was 3.31. This is substantially less coverage than found for the manufactured gas bonds on either a weighted or a simple average basis.
1183 Whereas, the average yield of Moody's Aa bonds for March, 1939, the comparable date for the gas companies, was 2.99 percent; the yield for March, 1939 was 5.51 percent on the gas series. Thus, the coverage actually available there on the average is not so different, but the average yield for these securities is markedly different.

The times interest earned for the 18 bonds was 3.74. Thus, the yield on Moody's Aa bonds, which is the classification in terms of coverage which most nearly approximates the coverage on these gas bonds, at 2.99 is substantially below the simple yield of 5.51 percent of the 18 manufactured gas company bonds.

Now, coming down to the bottom of the chart, the Standard Statistics curve employed on this chart is a simple average of the four quarters that are reported in the table; and of course the four quarters are the average of the respective months involved in the quarter. Thus, the curve is not at every point entirely identical with the other curve on page 10 because of the difference in the base of calculation. The principal differences develop in the point for 1931 and 1932, and there is a slight difference in 1934.

So far as that line is concerned, the caption ought to be amplified, that the Standard Statistics' index is the simple average of the four quarters for the year instead of the year-end figure. In other words, the average on page 10 is the average of December 20 yields and that on page 11 is the simple average monthly as reflected by quarters on page 18.

I would like to comment on the data shown on pages 13 to 17, inclusive. As of March, 1939, the weighted yield on the 18 manufactured gas company bonds was 6.14 percent, and the weighted times requirement earned, which is probably the legitimate and appropriate comparison to make if you are going to use a weighted yield, the weighted times requirement earned was 3.60. Thus, 6.14, the weighted yield as of March, 1939, and 3.60, the weighted coverage on the basis of 1938 income available, are in contrast to the yields which I previously quoted, the simple yield of 5.51 percent for the 18 gas company bonds as of March, 1939, and the simple times requirements earned of 3.74.

The 18 gas company bonds on page 12, for March, 1939, show a weighted yield of 6.14 and a weighted times requirement earned of 3.60. That is offered to contrast with and to complete the previous statement that the simple yield on these 18 manufactured gas company bonds as of March, 1939, was 5.51 and the simple times requirements earned 3.74.

Now, my being of the opinion that a period of this sort, with such rather markedly fluctuating yield levels, makes it dangerous to place too great a reliance upon any spot in the times series, I considered it worthwhile to establish the average or representative levels over this period of time for these various series. Thus, for the simple
average yield—I am speaking from the table on page
1184 12—for the simple average yield of 24 preferred
stocks, carrying it through from 1930 to 1938, accord-

ing to my figures the average is 7.98. Taking the 22 preferred stocks on a simple average yield basis—this is after eliminating the large low yielding issues—the average is 8.20. The 55 gas and electric company bonds on a simple average basis over this hectic period 1930 to 1938 average out at 5.46, whereas the simple average of the 18 manufactured gas company bonds gives me a figure of 5.72 over the period.

Now, in the light of what I believe with respect to the unfortunate influence of two of those bonds in the series of 18, I think we ought to add the average on the 14, which I do not believe is tabulated anywhere. The yield at the year end for the 14 manufactured gas company bonds for 1930 was 5 percent; for 1931, it was 5.98; for 1932, it was 5.79; for 1933, it was 6.86; for 1934, it was 5.48; for 1935, it was 4.66; for 1936, it was 4.24; for 1937, it was 5.68; and for 1938, it was 5.42, which averages for the period, to get a comparable figure for the more homogeneous 14 gas company bonds, 5.45 percent.

Pages 13 to 17, I believe, represent the listing of the issues included in the indexes that were discussed in the preceding charts. Found on page 13 are the issues included in the index of 18 manufactured gas company bonds. They record the bonds that were used in these series. These bond yields were always to maturity and preferred stock yields were straight yields.

The chart on page 19 and the two following charts are directed towards getting a closer view of the natural gas company position. I think possibly it will make it clearer as to what was done in each of them if I speak in respect to that whole effort. First, before addressing myself to that chart in particular, the first step in the development of the data on which this and the following two charts are based was to identify all the natural gas companies included in Moody's Public Utility Manual. After these had been identified the companies which had bonds outstanding were identified, that is, convertible debentures and any other security not a bond were excluded from the consideration of this particular study. All the companies having bonds outstanding then were checked in the Bank Quotation Record of the Commercial Financial Chronicle for prices on any Exchange, or in the public utility bond section. High and low prices were obtained whenever possible for each month. The problem, I may say parenthetically, with respect to a natural gas study is, I found, the same as expressed by some preceding witness; namely, the poverty of material to work with to get a really adequate and representative sample. That is the reason for starting out to take everything that is in Moody's and eliminate only what you had to give up, the effort all the time being to try to keep as large a mass of data as would conform to the necessary standards.

If only bid prices could be found the bid price was used instead of a sale. It, of course, is common knowledge that the bid would be lower than the asking price and is construed to be on the conservative side. It was in many instances, in a number of instances at least, the best that could be found.

The high and low prices for the month were found, were averaged, and the yield to maturity determined from 1185 standard bond yield tables. The yields for the three months in each quarter were then averaged to develop a quarterly yield. In cases where, for infrequent intervals, prices were available for only two out of the three months in the quarter, in order not to eliminate such bonds from an unfortunately narrow base anyhow, they were employed. Thus, upon occasion the average for a quarter is based upon two rather than upon three prices, in order to maintain the scope and breadth of the sample. In a very few cases where only one price could be obtained for a quarter, the yield on this bond was used in order to secure continuity of the series. However, there were very few cases where this was necessary, it it did not, in my opinion, affect the composite mass result at all. Bonds were excluded, of course, where no prices could be found.

Secondly, where the security became short term, it was eliminated. That is another difficulty with respect to natural gas security studies. Natural gas bonds are not usually issued for very long terms to begin with and then they soon hit the margins of a short term security and disqualify themselves because of the difference in the values of a short term security under these money market conditions. A default in interest payment of course excluded the bond before the default occurred. When and as soon as the security was called, the security was eliminated from the series.

By "short term" bonds, I mean maturities within five years. I think that is the standard accepted term, five years.

I think I can proceed with the rest of the explanation of the method used by reference now to the chart on page 19. The purpose of the graphical representation in the chart on page 19 and the chart on page 22, as well as on page 28, is to determine to what extent the experience with natural gas securities was comparable to the experience of the classes of enterprise previously analyzed. The purpose is to determine the range and representativeness and historical change of the yields on natural gas interest-bearing applications.

The vertical scale on chart 19 is the per cent yield to maturity, and the horizontal scale the years by quarters, and it will be seen that the quarterly yield was built up by averaging the monthly data.

Five curves are plotted on the field of the chart on page 19. The dash line identified as No. 5 records the changing weighted average yield of the total par value of natural gas company securities for which prices could be found and which conform to the conditions previously stated.

For fear of being misunderstood, I want to make one other limitation that I have made earlier, and that is there have always been excluded in these studies from natural gas averages any public utility company that was merely found to be distributing natural gas.

1186 The other four curves on page 19 are respectively, (1) the average weighted yield for the lowest one-quarter of the total par value. Now, this is a device which is a bit different and seemed to be made necessary by the range and variety of the security yields that one runs into in this kind of an analysis. So what was done was to take the total par values on which prices could be found in each quarter and array it from the lowest yield to the highest, then to measure from the lowest yield security up to a point representing one-fourth of the total volume thus reflected. Thus at each point throughout this series we are selecting the best one-quarter as evidenced by yield, which is a rather stringent and strong-armed way of separating a mass of this sort into representative quarters, in my opinion, however, the results are more representative than any mechanical division by characteristics other than the yield itself.

So the four curves, other than No. 5, on the chart on page 19, record respectively, (1) the average weighted yield for the lowest one-quarter of the total par value for which prices were obtainable in each quarter year, and (2) the average yield on the second lowest one-quarter of the total par value for which prices could be obtained for each quarter year. Similarly, curve 3 reflects the weighted average yield for the third quarter volume, and No. 4 the fourth quarter of the volume selling to yield the highest return.

In the middle of 1939 the lowest quarter was selling to yield an average of something under 4 percent, whereas the highest quarter was selling to yield in excess of 12 percent. The very range of the yields in data of this sort is what I consider makes necessary this kind of a breakdown, to show how representative an average curve, or how unrepresentative, for that part, an average curve might turn out to be.

The average in the second quarter of 1939 is 6.34 percent, but the range of yields which make up that average runs all the way from 3.58 percent to 12.29 percent.

I think it also would be helpful if I made this perfectly clear, that as a result of this method the same bond is not necessarily found in the same quarter continuously. Here we just admit to a membership in the quadruple class, the natural gas bonds if they merit it by being in one of the quarters at each time.

Obviously, you might hit $5,000,000, for example, and the quarter dividing the part would hit in the middle of it, in which case half of the $5,000,000 issue came in the lowest quarter and the other half went into the next quarter, since it is a division into quarters by the volume and not by the yield instance.

This chart shows that the spread in the average yield among the four quarters of the total volume was relatively small during the years 1928 and 1929. They hung fairly close together in those pre-depression years, surprisingly close for the performance over the rest of the period, but beginning in 1931 the possibilities for speculative fluctuation reflecting the greater degree of risk and uncertainty developing in general and in particular with respect to
1187 this class of investments becomes to be quite evident.

The statistical method employed here would naturally tend to stabilize index No. 1 very much, because it would always be privileged to have the cream of the total array included in it. Thus, we do not get the fluctuations reflected as much in the lowest quarter as in the second quarter, and of course very significantly in the third and fourth quarters.

The average yields for the second, third and fourth quarter volumes reached extremely high levels during the years 1931 to 1934, inclusive. The year 1936 reflected a substantial improvement in the position of these securities. The range in that year being only from four to 10 percent, if one may say "only" with respect to such a range. The relapse in the bond market of 1937, however, threw the curves widely apart again, from which they had recovered somewhat by the middle of 1939.

The yield levels reached by all but the best quarter of the total volume are not comparable with the experience of public utility securities, as far as the level is concerned. In the second quarter of 1939 the lowest quarter of the total par value by yield had an average yield of 3.58 percent, the second quarter of the total volume 3.89 percent, the third quarter 5.59 per cent, and the fourth quarter 12.29 percent, The average for the entire par value for which prices could be found in the second quarter of 1939 was 6.34 percent.

In the light of the hectic behavior of the securities of this class, it is not inappropriate to attempt to envision representative levels over a period of time. Over the entire period the lowest one-quarter of the total volume sold to yield 4.66 percent, the second quarter 6.14 percent, the third 9.29 percent, and the last quarter 14.73 percent. To reduce this to even more concentrated form it may be noted that the overall weighted average yield for the entire volume for the 11½ years was 8.71 percent.

Page 20 and page 21 record in table form the statistics on which the chart on page 19 is based.

1188 The chart on page 22 reflects a dispersion of each one of the yields applied in the preceding analysis. It is an effort at checking the representatives of the spread in the character of data employed. Averages of highly non-homogeneous statistical values are always possibly misrepresentative. In the chart on page 22 each yield used in the preceding analysis to establish four quarter volume indexes is plotted so that the actual range and concentration of yields at which natural gas company bonds sold during the period from 1928 to the middle of 1939.

The vertical scale measures the yields in per cent to maturity and the horizontal scale the years by quarters. Four designations are employed in this chart which should be distinguished. Each yield is indicated by a solid, filled circle, a black dot; the median point is indicated by a diamond; the first quartile point by an inverted pyramid; and the third quartile point by a pyramid.

Non-technically, the median would be the mid point in the array, and the first quartile would be a point one-quarter up in the array. It should be understood that a quartile is a point and not a quarter of a volume, as we used it before. It may be conceived as a quarter median. Median and quartile points afford an opportunity to trace representative levels that one may choose to interest himself in, and to trace the representative levels of yields as affording a contrast to the preceding weighted average yields which would always be influenced by the preponderance and size of certain issues.

The statistical tabulations on pages 23, 24, 25, 26 and 27 offer the supporting statistics on which the chart on page 22 is based.

This chart shows that for the years 1928 and, to some extent, 1929, a relatively compact distribution of yield between 5 and 9 per cent developed. The median for the years 1928 to 1929 ranged from 5.66 per cent to 6.80 per cent. The first quartile point ranged from 5.06 per cent to 5.61 per cent, but since 1929 the dispersion of natural gas company bond yields is obviously wide and irregular. While there was some reconcentration to be noted in 1936, 1937-1938-1939 again disclosed a wide dispersion. Thus in the period 1937-1938-1939 the median ranged from 6.46 per cent to 9.38 per cent, and the first quartile ranged from 4.40 per cent to 4.93 per cent. Again trying to condense a completely representative disclosure of this sort to a more comprehensible figure and to use some of these other measures here indicated, namely, the quartile and median points, I find that the average of the median points for the 46 quarters, that is, the whole period of the array, is 8.68 per cent. The average of the first quartile point was 5.14 per cent and the median 8.68 per cent. I did not assume to average down the list on the third quartile point. It obviously is a very much higher level.

1189 *Question by the Examiner.*

This is an entirely different approach from that reflected by the chart on page 19. On page 22 you have the actual yield by issues. In other words, the chart on page 22 is, in effect, an unweighted and simple representation.

Cross-Examination Interposed by Mr. Myse.

There is no attempt at averaging in the approach reflected by page 22. Every yield found is given its exact position. There is no boiling down. You have all the realism possible on this page, but the average on page 19 is a weighted averege. It gives effect to the size of the issues; and the quarter volumes obviously, in their location, are influenced by the size of these issues; but on page 22, in order to get around any influence of weight or volume, the actual yields in each particular instance are plotted to median and quartile points, merely indicated in order to allow for some following of the changing quartile points. Thus it is a median point to yields and not a mid point of volume. As explained before, this term "quartile" is a halfway point between the median and the top and bottom respectively.

Cross-Examination Interposed by Mr. Slaff.

You cannot always visualize the quartile point because it is sometimes over a dot, you understand. The statistical distinction between a quartile and a quarter of the range is that a quarter of the range has a volume in it. It is the amount from 0 to 3, say, whereas the quartile point might be 3.

Direct Examination by Mr. Morgan Resumed.

In the middle quarter of 1939, the last line on there seems to be 24 or 25 issues. The first 6 are separated from the second 6 by the quartile point. It is a technical statistical term used to mean just that, though I appreciate there is a good deal of confusion among people who do not use those terms.

In order to subject this material to one further test, all of the volume was arrayed by yield class intervals. Thus all the volume that yielded, at any time during the period, from 3 to 3.99 per cent was summarized. All the volume which at any time throughout the period yielded from 4 to 4.99 per cent was similarly summarized, and it was done that way down through the entire scale. This brings this rather widely varying data down to a somewhat more comprehensible basis, and also introduces the principle of evaluating it over the period of time.

Perhaps I can make it clearer if I point out that a given million dollars of bonds may have been sold at any one year to yield between 3 and 3.99, in another year between 7 and 7.99, and at another time between 11 and 11.99. If such a thing were possible it would find itself reflected in each bar in this chart at each interval. In other words, it is a composite of all the yields classified by the yield interval 1190 indicated in the scale, the horizontal scale on the chart.

The chart at the bottom of page 28 is the same material reduced to a percentage basis so we can see quickly the relative significance of the volume which sold at different yields. To summarize it in one sentence, it appears from that lower chart that approximately 23 per cent of the entire volume yielded from 5 to 5.99, and correspondingly the percentage of the total volume that yielded the different percentages set across the bottom of the page there is indicated. Approximately 45 per cent of the total volume over the period is shown to yield 5.99 or less, while 55 per cent of the total volume over the period is shown to yield in excess of 6 per cent.

It is clear that the mode is in the interval from 5 to 5.99 in the top chart and that the volume falling on either side of the mode is rather comparable, thus supporting the statistical position of the mode. I have made some observations with respect to the relationship of times requirements earned and yields with respect to these figures. Thus yields were obtained for the second quarter of 1939 for a par value of $151,779,000. The simple yield on this total par value was 8.69 per cent, for the second quarter of 1939, 8.69 per cent. The interest requirement on this total volume were earned an average of 2.22 times, that is, on the total volume on which the average yield was 8.69 the interest requirements were earned 2.22 times, that is, on this simple average basis. Now on a weighted average basis the yield on this total par value was 6.34 per cent, indicating the influence of the larger size issues for the second quarter of 1939, while the interest requirements on these securities on a weighted basis were earned approximately three times, again showing the influence of the weight of the large issues and the probably better average protection that they had. This is the second quarter of 1939.

Now I also offer figures which I do not believe I offered earlier in connection with the quarters for the total volume: Take the lowest quarter of the total par value—not the quartile point—the lowest quarter volume, which was in the second quarter of 1939, had a weighted yield of 3.58 and a weighted times requirements earned of 4.30. The second quarter volume had a weighted yield of 3.89 and a weighted times requirements earned of 3.66. The third quarter volume had a weighted yield of 5.59 and a weighted times requirements earned of 2.7, while the highest quarter volume yielded 12.29 and had a weighted coverage of 1.24. The weighted average of the total par value then had a weighted yield of 6.34 and a weighted coverage of 2.97. The simple yield for the second quarter of 1939 was 8.69 per cent and the simple times requirements earned of the whole 2.22 per cent. The supporting data for the charts shown on pages 19, 22 and 28 are shown on page 29 and 23 to 27, inclusive.

The charts on page 30 record the yields on public utility bonds of different risk characteristics as shown by Standard Statistics Indices of Public Utility Bonds. The reason for adding this series to the exhibit is that Standard Statistics divides the range into six groups as distinguished from the four groups of Moody's; consequently giving us a little more range. The average yields are recorded
1191 in the upper chart for the years 1924 through the
middle of 1939 for the six classes ranging from the highest grade A1+ down to the B classification.

This affords a check on the absolute differential analysis and the relative differential analysis which was presented based on Moody's statistics. Without taking any more time than necessary I think it would be sufficient to say that the absolute differences, as recorded in the second chart, confirm the result previously obtained. This further refinement, however, is to be noted in that here the differentials are as between and among classes, that is, each class is referred to a base which was something that was not done, you recall, with respect to the Moody's series where it was only the lowest class to the highest class. It confirms our expectation that if that basis were carried out in that page it would show the general trend of a widening absolute differential as you go into classes of securities having high risk characteristics.

Similarly, if you attend the chart at the bottom of page 30 it will be noted that the relative significance calculated on this same basis evidences a behavior very similar to that previously found, with a higher relative level of risk reward significance and with no approach in recent years to the low levels prevailing prior to the depression. The tables on pages 31 and 32 support the chart on page 30. I did not have planographed all the statistics on the absolute differentials and relative differentials which are found in the other charts.

The chart on page 33 records the volume of utility and non-utility domestic corporate long-term debt financing, classified as new and refunding by years. It will be noted that the public utility financing is indicated by the black and white segmented bar, whereas other domestic financing is indicated by the cross-hatched and diagonal designation. From this particular chart will be noted the very low level of any financing in the years 1931 to 1935 and the continued low level of public utility new financing during the period 1935 to date. The relative volume is indicated by the small black portions of the bars, and the point of contrast to which attention is called is the very low volume of new capital attracted compared with what was the fact in the period 1922 to 1931, when new public utility financing represented a very large part of all investment banking activities and when new capital was, as will be noted by the relatively small amount of white bar remaining, the preponderant portion of the financing.

The white portion of the bar reflects, of course, refunding, rebargaining for capital which has already established itself in its earnings power, whereas the new financing is the effort to get more capital into the industry. The table on page 34 supports the chart on page 33. The source of all these tabulations is the monthly report of the Commercial and Financial Chronicle of Corporate Financing.

1192 On page 35 the same basic chart is offered, with the superimposition of a curve showing the yield at offering price on new electric and gas utility bonds, that is, not new financing but new bonds issued, gas and electric utility bond issues. This yield at offering price suggests itself in the first instance as something of an index of the level at which capital bargains are being made by gas and electric utilities. It has, however, in my opinion, certain defects and is subject to misuse or misinterpretation, and I wish to address myself to some of those limitations. In the first place, a weighted average of the yields at offering prices of public utility bonds is influenced by all of the factors which go into that calculation, that is, the volume, the weight, the mere size and magnitude of the issues and the yield at which it enters. Consequently any such curve would not tell the whole story accurately if its qualitative content were changing over a period of time. It might be declining simply because a larger proportion of the kind of bonds which yielded less were included. In order to test that possible deficiency in a curve of that character the material reflected in the chart on page 37 is offered. Before leaving chart 35, however, I will state that the table on page 36 supports the chart on page 35.

In an effort to determine the qualitative character of these new bond issues in order to be able to appraise what kind of capital bargains were successfully made in recent years and at different periods, the financing of gas and electric utilities reported has been classified according to Moody's ratings. What is used is the first rating following the offering.

Now from the chart on page 37 it is seen that the Aaa bonds represented a relatively small and unimportant portion of the total volume before 1930; that even when you include the Aa bonds with the Aaa bonds they are still overwhelmed by the volume of issues of lower rating and classification; that after the year 1930 the Aaa bonds become a fairly important factor in the total volume of financing and when added to the next best class the Aa bonds clearly dominate the total volume of financing. Thus the Baa bonds, which were apparently quite salable in the period 1923 to 1928 and 1929, dropped into an insignificant position after 1930 and the Ba's and lowers practically disappeared from the scene of financing.

In the independent bar to the right of the chart on page 37 the average over the entire period is reflected. It should be understood, of course, that the average shown there for the Aaa bonds is tremendously influenced by the large significance attached to Aaa bonds in the later years, bringing up the very low level of the previous period very substantially. That affords a measuring stick or test of the relative significance. On page 38 the same chart is introduced with a different bar on the right. There is some interest in the question as to what is the distribution of utility bonds, in connection with what kind or class of

bond would be representative of public utility bonds outstanding. Consequently all the public utility operating company bond issues were classified by rating. The whole volume in Moody's was classified by rating, all those
1193 that have been issued during these years and any
that were hangovers during the previous years, in other words, what I would call the characteristics of outstanding public utility debt. We find that of the volume of all public utility debt outstanding, that which is represented by Aaa is slightly in excess of 10 per cent of the total. When reference is made to the yield on Aaa bonds, for example, you are talking about a class and variety which represents about 10 per cent of the total capital outstanding. Similarly, it can be quickly ascertained from the independent bar on this chart as to the relative significance of other risk classifications. The charts on pages 33, 35, 37 and 38 are supported by the tables on pages 39 to 49, inclusive. I would say there is just a slight difference between the volume of public utility gas and electric financing that is not rated and the total volume. It is not large, but there are occasional issues that are not rated. The chart on page 50 represents another effort to check the representativeness of the average yield on newly issued public utility operating company bonds.

The first distinction to be drawn is that between a weighted average and a simple average. We note that the issues of larger companies generally command lower yields; and so we contrast here the weighted yield which is represented by the solid line and the simple average yield which is represented by the dotted line. The middle curve, the sold black line in the middle of the chart, is the total yield on all ratings weighted. This is the same curve as appeared in the previous chart.

To break that down into its components a division was made between the average yield at offering price of securities which Moody's rated as Aaa and Aa, and those which Moody's rated A and lower, and the spread between the two groups of curves indicates the difference in the representative levels of those two classifications. One other thing, however, is to be noted upon more careful examination and that is in the early part of this period the overall average employed carried rather close to Moody's ratings for A class bonds and lower, whereas in the later period the average of all financing came down and was more representative of Aaa and Aa financing, which is the conclusion we suspected from our previous chart analysis. Consequently to a measurable extent the declining average yield of the new financing was influenced by the changing quality of the securities which were involved in the total.

In other words, the financing was confined to desirable issues predominantly. In fact, financing in recent times has been almost wholly restricted to securities which could qualify as the highest grade securities. Thus in the early period the number of issues of A and lower rating was very predominant, that is, 146 to 14 in 1923, for example; whereas, when we get down to the later period not only do the number of issues decline but there is an almost even distribution now between them rather than the overwhelming number which we had in the lower grade issues. The table on page 51 is the stastical data supporting the chart on page 50. In all these charts only the yield to the investor at the price at which the invesment banker, if such served, offered the securities to the investor is reflected.

Now it is quite appropriately observed, and must be before any conclusions are derived from any of these indicated levels, that the cost of capital to an enterprise is
distinctly higher than the yield to the investor. The
1194 highest grade securities in more recent years have
had to allow approximately one-fifth of one per cent,
if my recollection is correct, for the cost of financing as such. Consequently, the cost of capital to a company on the higher grades of financing would have to be increased by approximately one-fifth of one per cent on the average, and of course there is a considerable range in that.

When it comes to lower grade financing, securities that really have to be sold instead of being taken off the hands of bankers, securities not in the Aaa and Aa classifications, the cost of financing rises rather significantly and, in my opinion, would probably, on the average, run at least .4 to .5 of one per cent. When you get into securities of the class of preferred stocks, the cost of financing is even higher than that, so I do not mean to imply that these yields to the investors represented the full cost of capital to an enterprise. To these yields we always have to add the cost of financing to arrive at the cost of capital.

The charts on pages 52, 53, 55, 56, 59, 60, 62, 63, 65, 66, 68 and 69 I would like to treat as a group since they represent the same method of approach, differing only as to the period of time.

I stated in the course of the testimony that the yield as such on a security is little evidence of and by itself as to the capacity of the enterprise issuing that security to command capital, that finally and ultimately it is a question of at what price it can command the capital under given terms of the contract. Thus it is conceivable that the most risky and hazardous of businesses could command a certain amount of debt capital, a very small amount of debt capital, at rates which would compare very favorably with the rates on the highest grade securities of very safe and secure enterprises.

One of the most important and most common measures of the degree of security prevailing with respect to any investment security is the times that its interest requirements and the interest requirements of prior issues are covered. Consequently, in order to establish any kind of comparability, to get any kind of a valid measure of the credit position of an industry, it is necessary to go into a two-dimensional analysis and relate the yield and the times interest coverage of the security.

This method is employed in the charts on page 52 and following ones that were enumerated. On these charts the vertical line represents the yield to maturity at market price of the respective securities. The base line reflects the times interest requirements earned, or, reciprocally, the per cent of available income required for equal and prior issues. In order that it cause you no difficulty in reading it, it is always easy to reestablish equilibrium by noting that two times requirements earned is the equivalent of 50 per cent of available income required for equal and prior issues.

This series of charts is, in substance, identical with the series of charts developed by the Federal Communications Commission study of the rate of return in connection
1195 with the determination of a rate of return for the Long Lines Department of the American Telephone and Telegraph Company, with this addition: In order to test the relative position of the natural gas industry independent determinations along the same lines and following the same principles were employed with respect to representative natural gas securities. They were then plotted on these same charts, or charts redrawn from the same

data, in order to see whether or not natural gas securities conform to the characteristics of public utility securities.

Now in studying these charts the point is not to see whether they reach the same low level or not, but to determine whether, with the same amount of coverage and protection, they reach the same low level. Thus the method for reading these charts is to see whether or not a given class of securities falls above and to the right of issues of other classes. Thus, taking the chart on page 52, for example, which reflects prices for March, 1928, against the income for the year 1927, we find that the natural gas securities which could meet the qualifications and basis of selection employed for the Federal Communications Commission study are plotted, and it is seen that they substantially fall in an area on the chart both above and to the right of the mass of the gas and electric and telephone securities employed on that original chart.

There is added also to the chart on page 52 a line which you will find absent on page 53, a line which records the average yield of the middle six items of each of Moody's four grades of public utility bonds.

The open circle with the (1) in it represents the average yield and coverage of the middle six Aaa bonds; the open circle with the (2) in it the Aa bonds; the open circle with the (3) in it the A bonds; and the fourth one the Baa bonds. It is informative to note how these four grades of Moody's bonds, varying with respect to risk characteristics and coverage, distribute themselves through this field. The line connecting those four representative yields and coverage relationships is markedly below the level occupied by most of the natural gas bonds in this picture. The numbers refer to the supporting table, enabling you to exactly identify each particular plotted bond on any of these charts. Any number that runs up into 600 you will find at the end of the bond section here in a table listing all of the natural gas bonds. This number 649 is on page 71, I believe. It gives you the natural gas company bonds and this company is placed there for reference. The whole thing is coded for ready reference, both for the securities selected for the Federal Communications Commission study and the natural gas securities which were added to the picture.

There is one bond shown here at the 5% level in 1927 and 1928. That is number 649 and is a security of Southern California Gas Company, regarded as a very fine security in the market. It is so classified on account of the general position of the company, its other assets, and all the factors which enter into the classification of the security.

1196 Now the same method of reading these charts is employed with respect to each one. It will be noted that I did not attempt to impose the natural gas relationships on every year that the Federal Communications Commission employed. It did not seem necessary to make the point for each year. I moved from 1927 and 1928, which is a pre-depression relationship, to 1931 and 1932, which is pretty well into the depression relationship. In each instance the natural gas securities fall to the right and above as a group. I do not mean to imply that there are not individual exceptions.

I would not attach any particular importance to the specific location of any particular security in that array. The point to be made is the general placement of the classes of securities.

I would like to refer to the statement of principles and standards of selection for these bonds as reported by the Federal Communications Commission in its study. I have accepted their method of procedure as good and reliable and have employed it here. We have attempted to apply the same standards to the selection of the natural gas bonds.

I point out that on the top of pages 55 and 56 some decanterlike figures appear. It seemed desirable to maintain a field for the plotting of those so that the eye would envision similarity of relationship and placement identically from one chart to another, but in certain years here these natural gas bonds got completely out of hand, at least some of them did, and went off the chart, so instead of destroying the opportunity for a ready visual comparison and keeping the same size field we simply indicated they were 9 per cent and above and let it go at that.

Now the chart on pages 68 and 69 without the Moody index on it is not a chart from the Federal Communications Commission study. That study, as you know, was made before that time. In order to make available the data for more recent periods for this purpose the same technique and procedure was employed to project the Federal Communications study and bring it further up to date. I had access to the Statement of Principles and the methods of selection as a guide to making that as comparable with previous tabulations as it could be made. I still find the natural gas bonds above and to the right. Some of the natural gas bond yields have come down to much lower levels than previously existed; but it is always to be noted that for the same coverage, for the same income protection, natural gas bonds are found to lie higher in the field.

The tabulations following each one of the charts from 52 through 69 are shown for the purpose of supporting the charts.

Cross-Examination Interposed by Mr. Slaff.

In getting the middle six Moody's for each Aaa and Aa it was necessary for the Aaa group to avoid extreme instances because in Moody's 10 bonds they had bonds in there that had 17 times coverage, for example, a few freaks like that; and so the middle six proved to be a more homogeneous, comparable group. But since it was neces-
1197 sary to do that, to get rid of the freaks in the Aaa classification, it seemed desirable to do the same thing for the other classifications even though the freak coverages do not appear in the lower classifications. That was an effort to get closer approximation to homogeneity and representativeness.

Direct Examination by Mr. Morgan Resumed.

On pages 72, 74, 76, 78 and 80 the same technique has been employed with respect to preferred stocks. Again the chart for the last year is designed with the highest regard for the principles and technique employed by the Federal Communications Commission in its study; and in these charts, as in the bond analyses, we find that for yields which are identical the coverage on natural gas preferred stocks is higher. Thus cartographically they are found to the right and above the levels characteristic for gas, electric and telephone securities. The tables accompanying these charts in each case offer the names and the identification numbers.

On page 83 a chart is offered which brings together in one place the relationships of yield and coverage for the Moody's bond classifications previously employed. The curves are for each indicated year; and there is developed also a composite curve representing the 12-year average for the Moody's series showing the relationship of yields to coverage. I refer there to the heavier black line falling in the middle of the field. For a period such as the last 12 years a composite result can be relied upon to eliminate the accidents of the particular year, and what accidents of inclusion or exclusion may have existed.

Thus the shape of that curve and the characteristic relationships there is probably a rather significant overall representation of what is required in the way of protective earnings or protective income at given yields for the class and type of bonds which Moody's used in their series.

The last chart, which unfortunately escaped numbering, which should be 85, imposes an additional curve on this chart for comparison purposes, using the prices for March, 1939, and the income for 1938 in each instance: We have the distribution of the gas and electric bonds as before. We find the natural gas securities plotted to the right and higher in the field. We have the curve reflecting the Moody's times requirements earned for the four risk classes; and in addition the yield and coverage by quarter volume of natural gas bonds that were developed earlier, plotted on here to see where they fall in relation to the public utility distribution which was developed.

I have used Exhibit No. 152 in arriving at my judgment as to what constituted the fair rate of return for defendants.

(At this point EXHIBIT NO. 152 was offered and received in evidence without objection.)

Having made the investigations included in the qualitative and quantitative analyses which I have reviewed here,
taking these analyses and the facts which I have de-
1198 duced and developed therefrom, and taking into ac-
count my knowledge of the natural gas business and the business characteristics and hazards of the particular gas companies involved in this hearing, and also my knowledge from experience and training in the field of economics and financing, my knowledge of the general business conditions of the country, and the earnings or yields which capital invested in business as a whole and in the natural gas business in particular is entitled to earn in order to command the required capital to conduct business and to compensate for the use of that capital, I have an opinion as to the proper rate of return for defendants.

My opinion is on the basis of the material of the qualitative and quantative character presented here, on the basis of past experience, on the basis of all my exposure to the effects of capital bargains that have been made for industries in this country. I have approached the development of a rate of return for the natural gas industry from the standpoint of the public utility industry and by noting the differences and distinctions rather than moving down from the industrial classifications to the natural gas situation. I would like to put my answer in this way, if I might, that if there were an enterprise engaged in the natural gas business having a large, substantial investment in natural gas resources and in specialized transportation facilities, which company had the protected position and status of a public utility, I would consider 8% an adequate return; but I am of the opinion and conviction that Natural Gas Pipeline Company of America and Texoma Company do not qualify economically as a public utility, that the conditions and circumstances of their operation are not comparable to what is found in a public utility, and that those distinguishing economic conditions deserve recognition, in fact, must be recognized, in my opinion, if one is trying to judge what the necessary supply price of capital today would be for an enterprise of that character. Moreover, assuming that there is recognition to be given to the reward of enterprise in an undertaking of this sort, and that there is a desire to compensate and induce enterprise, I feel that 9 per cent is a more appropriate and fair return.

By "public utility" as I use the term here I mean an enterprise engaged in distributing a necessary commodity. I do not mean to attach any significance to whether an industry happens to be labeled a public utility as such or not.

Preliminary Cross-Examination by Mr. Booth.

If fairness is to be construed as including the reward for enterprise, then I say that a fair rate of return for these companies is 9 per cent. I do not say that the reward for enterprise accounts for the difference between 8 per cent and 9 per cent. I think I have put my answer to indicate that there were two considerations which entered into that difference: (1) the absence of the economic characteristics of a public utility undertaking and (2) the offering of some inducement and reward to enterprise. These two elements account for the distinction between the 8 per cent and 9 per cent to which I refer.

I did not attempt quantitatively to measure and express in my mind the difference between 8 and 9 per cent. I do not find that the mental processes of valuation are
1199 subject to that kind of quantitative fractioning. I
think any effort to do so usually is under pressure

and reflects a degree of straining of the processes of judgment. I have not divided the figure representing the difference between 8 and 9 per cent into a specific allowance for the reward for management and the elements which distinguish it from a public utility enterprise. The process of coming to an opinion on the basis of a wide range of facts and material and exposure through a period of time is not subject to a calculating machine type of mental demonstration. I gave consideration to all these factors and came to an opinion. I did not build that up as bricks would build up a wall or assign specific mathematical quantities to each of these items.

Earlier in my testimony I stated that the rate of return must be divided between pure interest, risk premium, allowance for uncertainty, and finally the element of watchfulness, the care of the investment, stating in that connection that these were qualitative factors which should be recognized and considered, that they are generally significant and should be considered. I recognized those factors and gave careful consideration even to the question as to whether or not at this time there was any significant change in the evidence; and purported to show that such a thing as pure interest is not reflected ever in a quantitative expression in the market.

I did not engage in such calculating machine allocations as the assignment of a specific portion of the 8 or 9 per cent to pure interest. I cannot state how much of the 8 or 9 per cent I would allocate to pure interest. I think any effort at such a decimation of a composite figure is straining the processes of judgment. My most elaborate efforts have not disclosed any market indication of the price of pure interest as such; and I do not know any one else who has ever caught a market expression of pure interest as such. I think that it is definitely straining the processes by which one arrives at judgment to attempt specific allowance for pure interest and the other elements which comprise rate of return. I have always been of that opinion. I have sometimes given weight to estimates, approximations, in a retroactive fashion of analyzing back, but with full appreciation and knowledge that the process is a strained one.

I cannot state that in the course of my testimony I have referred to every important factor which I considered in arriving at my judgment as to what constitutes a proper rate of return for these companies because I understand the processes by which the human mind works. There are many considerations which enter into it and leave their impressions in the course of a person's making up his mind. He is not necessarily, at a given moment, aware of all of them. I have not, if this is the answer to your question, offered or presumed to offer in my testimony many factors which undoubtedly have an influence on an individual's final opinion and judgment in a matter of this sort.

I began working on this study some time in April. I do not have in mind the number of days but I can assure you it has been on my mind more days that I have ever had recorded as definitely employed. It has been on my mind while I was traveling and while I was doing other things, as well as the formal time, which was substantial.
1200 I imagine direct and formal application probably runs into two months. I wrote up statements and opinions over the range of the subject matter which I thought were probably appropriate for the purpose in the course of my preparation. I prepared this exhibit and I developed, as I went along, opinions about different aspects of the thing as they developed. I am quite certain there must be important factors which entered my mind in arriving at my judgment as to the proper rate of return for these two companies to which I have not testified here because I could not possibly, in this time, cover all of the considerations which enter into that sort of thing. As to whether or not I have testified to all the important considerations, that word "important" is a relative term. I do not think I could put myself under such a restriction and extemporaneously say that there were no other important considerations which, in the course of coming to such a conclusion, entered into it. I am fairly confident that there were.

I just got through saying I certainly would not want to put myself in a position of having to recall extemporaneously all the things which were given consideration over a period of time like that. I am very confident that there were considerations which I have not mentioned in my testimony. I do not want to give a categorical answer which is not accurate. That is my only hesitancy. I was given a perfectly free hand to develop any material that, in my opinion, had a bearing on the question. I was given no instructions of any sort otherwise and to the best of my knowledge I went ahead and dealt with the evidences that were obtainable and tried to work up the best of them and present them. There are certain things which I consider of importance which I have not testified to. For example, I testified this morning that I think a general observation of the earning power of capital as a whole is something worth taking into consideration. Now I did not do that and I did not directly in my own words testify to that particular thing. I had it in mind but time and energy would not permit special treatment. I, frankly, exhausted myself doing this, in addition to other duties, over that period of time. I just want you to understand that there are things that I would probably do in addition to what I have done if I had the time and opportunity.

I did refer to the earning power of capital over industry as a whole in a secondary manner in discussing a portion of the exhibit prepared by Mr. Gilman. It was opinion evidence on things prepared by another witness. Obviously it was my intention to refer to the matters of consequence, significance and importance, but where importance ends is an open question, and I was simply carrying it from one thing to another. I would like to make this additional statement, which I made privately to Mr. Slaff, or others, that in my appearing in a hearing of this sort from a university position I felt rather impelled to take something of a broad gauge point of view and to attempt to contribute something; and I would like to say in that connection to some extent I rather dodged doing too much of the traditional thing as part of my contribution today.

1201 I do not recall whether I made any direct reference to the changed circumstances of recent weeks, apparent changes in the policies of the Federal Reserve Board, as indicated by the withdrawal of support from government bonds, or to any direct evidence, which is probably significant, of a prolonged conflict. I did not take time to draw parallels between the experience that is evolving now and what developed in the course of the last great war. That may well come up as a fairly important thing. It is developing day by day. I am conscious of it. I am beginning to feel it may prove to be a very important factor. The day government bonds dropped I was very conscious of the significance of that as the possible beginning of the readjustment in money markets in this country. If that is the kind of thing, yes. That was a consideration hardly of the calibre which should be brought in, or hardly unique enough to be woven in with a discussion of the kind I tried to offer, but possibly it would classify as an important consideration. I am perfectly aware and conscious of the fact that there is a threat and impact here which may be of important consequences for the security markets.

I think that probably my testimony did not indicate the degree of significance that properly attached to what experiences of investors in general have been throughout the period of changing economic conditions. It is one of those general things that every one is more or less conscious of and which more or less go without saying, but that does not diminish the significance or importance of this sort of thing in a consideration of this character.

I am not sure whether I called appropriate attention to the fact that the period of time over which the investor is willing to commit his capital to natural gas enterprises is apparently quite short. I found, as an incident to the development of my own studies, that bonds were usually relatively short term. For a considerable number of years 10-year bonds seemed to be the rather standard and traditional period, indicating the unwillingness of the investors to project themselves very far in that respect. Moreover, even in those relatively short term bonds they very commonly carried with them a stringent or strong amortization provision, so that in many instances what looks like a 10-year bond on the record is not in reality a 10-year bond, by virtue of the operation of the amortization requirements on the company's loan. The loan being for 10 years, the term averages only 5 years for the full amount, thus reducing the term by approximately one-half. The fact that investment banking found it difficult to sell securities of natural gas enterprises unless they were protected in that peculiar way I think probably has not been adequately emphasized. I am perfectly conscious of it as a fact.

It indicates the attitude of the investors toward the risk and uncertainty, and risk of the possible termination of the life of an enterprise of this sort.

I think that is one of the evidences of what I have called a major underlying factor, namely, the terminable life,—
not only terminable but terminable over a relatively
1202 short period of time, and a high degree of unpredicta-
bility within that range as to what it is really going
to be. What I referred to was merely to weigh the out-

ward evidences or weigh the market reflections of the investors' reactions towards that condition.

I made no geological determinations as to when the life of the reserves of these defendants would terminate. I think my testimony is perfectly clear on that. I stated that, from an economic point of view, all estimates as to physical life and all attempts at estimating economic life were subject to so many variations as to constitute, in the mind of the investor, a distinct hazard, because of the very uncertainty of any estimate of that sort.

I made no assumptions as to the length of time. I testified as to the amount of insecurity and uncertainty created by the various difficulties of making such estimates. I think this aspect of the terminable life of the enterprise or of an enterprise of this sort is a very fundamental consideration. I have seen the estimates that have been made as to the life of the property of these companies but I do not know as I recall whose estimates are whose. I think there were estimates running, if I recall correctly, 14 years, or something of that sort. These estimates were made presumably to show the life of the field which is being employed for this particular enterprise. I do not think I know the people who made those estimates. I have not said I was familiar with those estimates. I thought I recalled what the range of estimates had been. I have made no estimates as to the life of this project nor did I use any estimates in making my determinations as to the rate of return. I do not remember what the estimates made by other witnesses are. I have exposed myself to them. I read them in the testimony or in something else; but for the moment I would not be sure what my recollection on those is.

To an extent I am familiar with the company's capital structure. It consists of bonds and stocks. I have some recollection that the bonds ranged from $45,000,000 to $47,000,000 and that the amount of stock was nominal in relation to debt capitalization. I do not remember the number of shares. I do not recall if the shares were of a par value or approximately $3,000,000; I would have to look it up. The bonds, if I recall correctly, are 6 per cent coupon bonds, which I think I testified is of little significance under the circumstances. These bonds are held by the participating parties in the enterprise, I understand. Refinancing is a normal experience. Companies issue debt obligations of limited term of life and they naturally have to refinance. There has been that refinancing in recent times. You ask if it is a common practice of public utility and some industrial corporations to refinance their outstanding indebtedness in the past two, three or four years. If you will leave out the word "common" I will answer "Yes", they have been refinancing for the purpose of getting lower money costs, lower interest rates and because of their maturities.

There has been a rather considerable amount of anticipation refinancing,—if you would use that term I would know what you are driving at,—anticipation refinancing on the part of the best utility companies, with respect to the highest grade and class of securities. I attempted to make clear in my testimony that the overwhelming proportion of the financing—and most of it was refinancing—was
1203 of the highest grade. That is the type of bond that you could refinance. Over a substantial number of recent years it was not possible to do any other refinancing.

I did not say that I was employed by a financial organization in about 1929 and 1930. I was an economic consultant during that period in New York; and I did a great deal of work for the old banking firm of August Belmont & Company in those years. This work was done on a semi-independent basis. I had an office up on the tenth floor of the same building. I had dealings with Rollins back in the days of the utility consolidations. That firm is entirely reorganized now; and it is an entirely different organization really, with nothing but the name left. I did a good deal of work for an organization known as James Rorrison which was a purveyor of utility preferred stocks. I did a good deal of work in reorganizations and plans for the firm known as Pomeroy & Salmon during the period of the banking distress. I covered a good deal of the South in that connection. That was a New York firm. I have had individual consulting contacts with various firms on utility matters. It is difficult to remember at this time of the day. I want to make it clear that I had offices of my own primarily during most of this period, either the Cedar Street office in the Life Insurance Building or the Continental Bank Building where I was for a year, I believe, during that two-year period. I had a multiplicity of industrial contacts which I will try to dig up for you which covered a range of a great many different types of industries and businesses. I think a substantial portion of them were in my own interest.

One of these contacts was in the industrial gas field. I had an assignment from one of the partners in Belmont & Company to determine whether or not it was a good idea to take a look at the natural gas business at that time. I think it was in 1930. The paucity of other activities and the difficulty of doing business suggested looking into possibilities, and I recommended an exploratory attitude. They did send out a number of men and retained engineering firms to make an exploratory determination. The net result of it was a decision not to have anything to do with it. I think the engineering firm we retained was Ralph Davis.

In answer to your question as to what seemed of most significance in arriving at my judgment as to what was the proper rate of return for defendants, without presuming to measure in a mathematical fashion and appreciating that I cannot do anything different in a thing like this than the buyer of an automobile can when you ask him "Was it the style or the horsepower that influenced you most, and how much?", I think I can safely say that the risk and the uncertainty elements in the situation stand out when compared with any other one. I think it is a fair statement to make that these two factors are more important than the element of pure interest and the other two factors to which I referred. I thought I testified clearly on what I think is the most important consideration in the factor of risk. I am glad to repeat it. I think my most summary statement on it was that the uncertain life and the behavior of natural resources imposes its uncertainty and risk on the whole investment, since it is 1204 dependent upon that resource situation, but you may recall that that was not by any means the complete statement. Then I divided my answer into two parts dealing with the conditions maintaining at the source of supply and those maintaining at the point of delivery. I analyzed it in terms of the circumstances influencing the certainty, reliability, continuity and cost, and availability of the physical supply on the one hand and the circumstances and characteristics maintaining with respect to the market on the other hand, knowing that a piece of stem pipe line between those two situations is of course helpless to have any determination of its own. It sinks or swims with what happens on the two important ends of the business transaction, the supply of goods or the behavior of the demand for the goods. I consider that the whole combination of circumstances with the conditions prevailing at the source of supply and the conditions prevailing at the other end, and the fact that you have got a substantial investment in a perfectly helpless piece of capital equipment which has no alternative use but to rely upon the continuity of supply or continued availability of a profitable market to constitute a combination of risk uncertainty elements and economic hazard which is, I believe, quite unique

I did not say that this was a single element. It is the combination of all those circumstances running all the way from the source of supply to the circumstances of the market; and you will recall that I have included in the consideration of the circumstances prevailing in the market the divorce from the control over a merchandising policy in the market.

I thought I had done a fairly thorough and complete job on that subject in my direct testimony. I am of the opinion that I expressed myself rather adequately on the range of hazards and uncertainties prevailing all the way from the fields to the market.

I did not hear all of Mr. Delafield's testimony. I heard a great deal of it. I am not sure that I heard Mr. Delafield state his conclusions that not less than 8 per cent would be a proper return for these companies.

I tried to make it clear in connection with another question, the one that Mr. Slaff was having trouble with earlier about pure interest and bond yields, that pure interest might well be higher than an indicated bond yield on a fairly riskless investment. Let us assume for theory purposes a riskless investment. People might be willing to sacrifice, under given conditions waiting for a critical time, pure interest in favor of liquidity, and that is why I could not answer your question earlier in the form in which you put it to me. It is not necessarily true that the pure interest coincides with the yield on a riskless bond.

I do not see how I can go on record as agreeing with Mr. Delafield because I cannot begin with the premise of the measurement of pure interest in that form. As I said later this afternoon there is no objective market expression of the concept of pure interest as such. It is an element of loan interest but it is never sold in the pure form of and by itself; and I definitely testified that I did not 1205 accept the generally loosely accepted proposition that the yield on government bonds represents pure interest.

You ask whether or not approximately two years ago in connection with my testimony before the Illinois Commerce Commission as to the rate of return of Peoples Gas Light and Coke Company I stated the rate of return I had fixed was divided and 3 per cent allocated by me to the element of pure interest. I do not believe that accurately states what I testified to. It is a long time ago and you have looked at the record and I have not; but knowing what I think and how I have always thought, I would be rather doubtful that I put it in that form.

Referring to the language you have read to me which you state to be from pages 9272, 9273 and 9274 of the transcript of the case of the Peoples Gas Light and Coke Company before the Illinois Commerce Commission, reading as follows:

"I think that 3 per cent is a fair per cent to use for pure interest in the make up of the 7 per cent. The portion of the remaining 4 per cent allocable to risk is a matter of opinion. I would be inclined to believe that the return available to capital in an industry of this sort as a whole, and the type of company performing work * * * that the risk and uncertainty at any time over and above pure interest certainly would reach, well, to the 3 per cent level."

part of that quotation sounds familiar and part of it sounds as if somebody wrote it who did not understand his economics too well, to tell you the truth. My recollection of that, Mr. Booth, and this is only my recollection, is that you were asking questions along similar lines, trying to secure a quantitative identification; and my recollection is that I made substantially the same answers indicating that you were invading a field of judgment and that these things were not reducible to quantities in that fashion. Your persistance may finally have won a degree of compliance in the form of saying, "Well, 3 per cent is often thought of as representing that" and if you wanted that, all right; but I knew perfectly well then, as I know now, that there is no objective market reflection of pure interest. That is the best of my recollection at the moment. I have not seen or thought of that record since that day. It may be in my office. I think I got one once but assure you that I did not open it. I would not be sure whether I have what was given or not.

Mr. Delafield in his testimony apparently did combine in his answer two things. If I understand the pertinent paragraph, it is this:

"I said in the direct testimony that a good measure of pure interest at the present time was the rate on the bonds held by all New York savings banks which in 1938 was 2.87. I should think that between 2¾ and 3 per cent of the 8 per cent in that range would be pure interest and the balance risk premium."

That is a combined answer and there is much in there that I cannot agree with. I do not think that the return 1206 on the bonds held by all New York savings banks is a measure of pure interest; and I do not think there is any objective measure of pure interest, as I have stated many times. If there could be a measure I do not agree that this would be the measure because savings banks are practically bomb cellars for capitalists just scared and hiding there. That is not the people's time preference at all. I disagree with it. I cannot follow the line of reasoning that between 2¾ and 3 per cent of the 8 per cent is pure interest. Mr. Delafield did say on page 5175 that his best judgment is that 8 per cent would be divided into approximately 5¼ for the risk premium and 2¾ for pure interest but he adds, "But I would not necessarily have to divide them 3 and 5". I agree with that. I have grave doubts whether that statement is accurate and I think if I have to accept this procedural analysis that I would not be inclined to take that position, taking the position primarily that that is not determinable in that way. A man may have an opinion of that and it might be perfectly legitimate; and he may think of pure interest as Mr. Delafield thinks of it in terms of a riskless investment. I have not any quarrel with that; those are his mental processes by which he arrived at his judgment; but I just cannot do it that way.

Question by the Examiner.

I do not believe that a question of this sort is reducible to that sort of a quantitative breakdown. We have no objective evidence as to what pure interest rate is. We have economic bases of thought and analysis which establish our presumptions and notions as to how that phenomenon is probably behaving under different sets of circumstances or facts; but that is still a long way from saying that in February of this year it is this much and in March of another year it is that much. We know what influences people's saving dispositions, for example, Mr. Examiner. Suppose you are facing a threatened inflation. We know by the study of historical experiences that in the face of threatened inflation people's disposition to save for the future goes all to pieces. That is a common social economic phenomenon.

It enters into my figure of 8 per cent as a factor recognized as making up the measurable phenomena of loan interest. It is one of the elements in the thing which is objectively expressed, namely, loan interest.

Cross-Examination Resumed by Mr. Booth.

If my answer is properly construed I would be willing to go into the question of whether 2¾ per cent was high or low as to the element of pure interest today. My personal opinion is that it is probably low as of present enonomic circumstances. I have probably a conclusion in the direction of opinion that the market value of time preference has gone up. There are a great many factors which enter into that. It would involve an analysis of our whole institutional setup and our social and political organization.

Take for example the psychological effect ultimately of society taking over the responsibilities of old age, the development of comprehensive plans of social security.
1207 That is having a psychological effect on people's dis-
position to save, which I believe is something we are going to have to reckon with. Factors of that sort influence phenomena as fundamental as time preference. The distribution of wealth among a people has been recognized from the beginning of the science as an important factor. You get a concentration, and there is ease of saving and accumulation of capital. You get a more equal distribution and we note the opposite phenomena. Thus for example that would give some basis for believing that we are headed toward a higher pure interest factor and that is not a wholly theoretical consideration. It is observed by such practical financial analysis as Chamberlain in his old edition of Bond Investment as to what influences the interest

rate on bonds, and he notes the distribution of wealth among the people of a community.

A wide range of social economic factors of that sort enter in, and in passing judgment on how the pure interest element is probably going, you may recognize and consider those, but that still is far from getting any market evidence that it is 2¾ or 3⅛. I would put it the way I did put it. I think there are a great many forces operating to advance the pure interest rate to a higher level. I do not know whether 2¾ per cent is higher or lower than the actual figure but whatever it is I would be inclined to believe that it is headed for higher levels.

I have testified that I do not believe the yield on long-term government bonds is acceptable evidence of pure interest. I have testified that I know that there is no objective market evidence of pure interest.

I know that the bonds of defendants are held by the equity holders or stockholders. Since refunding those bonds at a lower rate of interest is entirely almost a transaction of the right hand with the left hand, I do not see that there would thereby be anything involved one way or another as far as the equity holders are concerned. I may be wrong about this observation, but I think that there is an income tax advantage in having a deductible interest charge which is obviously a payment out which you you can save yourself on to some extent; and if I were involved in it I simply would determine as a matter of fact whether or not I am not saving money by having these bonds outstanding.

I do not recall that I ran across any suggestion that defendants had made any effort to refinance their bonds, outside of apparently somewhere in the record I recall reference to a contemplated public financing or contemplated issue of these bonds at some time which apparently was found impracticable under the market conditions and it never transpired. That is the total recollection I have of any reference to financing. I don't believe I ever talked to Mr. Brown about that.

1208 **FLOYD C. BROWN**, a witness for defendants, called temporarily by Mr. Booth, testified as follows:

Cross-Examination by Mr. Booth.

You ask me whether or not the company has made any effort to refinance its securities. What do you mean by "attempt"? As far as I know the company has never considered the situation just expressed by Mr. Dorau, namely there being an income tax advantage to the company in retaining its present capital structure. I do not believe the company at the present time has any definite plan in mind for refinancing its securities. I would not say that we have not had such a plan in mind during the past one or two years. We have discussed from time to time the public financing; but for one reason or another any thought of doing public financing has been dropped. As to whether or not it would make any difference to the position of the present equity holders if the company refinanced its bonds at a lower rate of interest would depend on whether there was any public financing or not. Otherwise I think it would involve a matter of some accounting, probably a matter of analyzing the tax laws and determining whether the deduction for interest as an income tax item was offset by the tax upon undistributed profits or dividends, as to whether the equity holders received their money in dividends or in interest. Those are all matters that would have to be considered. We have not considered those matters in the connection as to whether we should do any refunding or not.

1209 **H. B. DORAU**, a witness for defendants, recalled, testified as follows:

Redirect Examination by Mr. Morgan.

Referring to the language on page 5120 of the record here when Mr. Delafield was asked the question:

"How do you find out what the pure interest is in an investigation of this sort," and he answered—

"Well, it is very difficult to put your finger on the exact 1/100 of 1 per cent determination of what pure interest would be at any given time. There are a great many measures. By applying many measures, you come to a judgment figure. It has been frequently done, it has been done over a long period of years. Ordinarily, you would look to the yield of very high grade securities, as for example, government bonds. Now, you frequently have periods as you have had, in my opinion, in the last seven years when government bonds generally for a multitude of factors, sell at much less than the pure interest rate. There are other factors in there.''

I think that is an infinitely better statement than the one I was offered as a basis of comment. I think I could be in substantial agreement with that.

(October 23, 1939)

(At this point the Examiner announced that the items relating to lands in fee and rights of way in Exhibit 125, temporarily excluded at the time Exhibit 125 was admitted in evidence, would be admitted in evidence. The counsel for each of the two Commissions objected and were allowed exceptions.

(Motion to strike Exhibits 141 and 142 by counsel for the two commissions taken under consideration.)

1210 At this point the following letter written by defendants' witness J. A. Emery to the Examiner was incorporated in the record:

Ford, Bacon & Davis
39 Broadway,
New York.

October 11, 1939.

Mr. E. G. Simpson, Examiner,
Federal Power Commission,
Washington, D. C.

Dear Sir:

As requested by you, I have examined the available data relating to Southern Natural Gas Company, Union Gas of Canada and Lone Star Gas Company to see if any reason is apparent for a lower rate of return on the market appraisal of the securities of the Southern Natural Gas Company than the return on the securities of the other two companies in 1938.

In 1938 the Southern Natural Gas Company increased its compression equipment so that it raised the carrying capacity on the main line from 125,000,000 cubic feet per day to 145,000,000 to meet the requirements of important additions made to the steel manufacturing plants in northern Alabama. This naturally held out the promise of greater earnings and would account for somewhat higher prices and, consequently, lower earnings-price ratios based on the earnings of 1938.

Very truly yours,

(s) J. A. Emery.)

1211 J. A. EMERY, a witness for defendants, recalled for cross-examination, testified:

(October 23, 1939)

I would like to make a couple of corrections in the record, if I may. The record reads that Mr. Hill was president of the Interstate Natural Gas Company. Mr. Von Puhl of our firm was the president, and Mr. Hill was manager. The record reads that Mr. Hill was president of Southern National Gas Corporation. He was vice president and general manager. The record also states that the Interstate line was 22-inch and 18-inch. The main line was 22-inch, and the line from Baton Rouge to New Orleans, owned by Southern Gas and Fuel Company, a subsidiary of the United Gas Company, was 18-inch.

Cross-Examination by Mr. Slaff.

I have gone over most of my testimony on direct. There are some parts that I have rather skipped over. I have had Mr. Timberlake and some others in our office go over it carefully. The corrections which I have just stated, outside of some corrections in English, are the only corrections I have to offer with reference to the transcript.

I should say that I am a professional witness or professional expert. That is to say, an important portion of my work is the supervising and preparing of testimony for rate cases and testifying in rate cases. The majority of my testimony is on behalf of public utility companies, using the term generically. All of my testimony relating to going concern value or rate of return has been for companies of that character, except possibly one case in which the City of New York was interested. That was the Interborough tax case. I testified for the Interborough, and the city was interested on the same side of the case. I was retained in that case by the receiver of Interborough Rapid Transit Company and testified for him.

The case involved the value of the lease by Interborough of the original subway in New York for the purpose of an amortization deduction in their income tax return. I don't remember whether a refund was involved or not.

I am being paid by the defendants in this case. During the year 1938 my firm received $20,000 in fees from this company. All of that was in connection with my services on the subject of rate of return and going concern value. According to my recollection the total amount now is about $32,000 for the two years. I don't know whether all of that has been paid or not. The amount of the last bill, I think, was $4,700. I receive a per diem fee under my contract with defendants. I don't remember what this per diem is. The standard rate for my time is $150 a day. I think that is the rate in this contract, but my recollection fails me. On this case it is my recollection that that per diem applies on any work whether at the office or in attendance at the hearing.

1212 The members of my organization who devoted their time to this work were paid varying amounts. There is no additional charge or loading of the contract for Ford, Bacon and Davis overhead. The bill covers only the salaries and actual out-of-pocket expenses. I prepared the testimony and am testifying here because I was paid for the work.

We own a considerable quantity of stock in the Southern Natural Gas Company, and naturally that stock would be affected by the rate or return allowed in this case. Our firm owns 20,000 shares of the new stock of Southern Natural Gas Company. We formerly owned approximately 40,000 shares of Class A and Class B stock. This stock was called in and new stock was issued. We were among the largest stockholders in Southern Natural Gas Company prior to the reorganization.

If Southern Natural's registration with the S. E. C. shows our company to have been the largest stockholder of the Class B stock, I would accept that statement. Our firm has a representative on the Board of Directors of Southern Natural, namely, Mr. Von Puhl. We no longer have the management of that company but are retained as consulting engineers. That company is subject to the jurisdiction of the Federal Power Commission, I understand.

The rates of earning on settled enterprises are probably somewhat lower now than they have been in the past. I think the rate of return required for what is called "venture money" would be probably higher than in the past. I make a distinction between venture money and money invested in an established business which has a history and is developed. I should say the rate of earnings of business of the latter type are lower. My conception of rate of return depends on the rate of earnings to a large extent, as the exhibit I have presented on that subject shows. I think the rates of return on that type of business are lower at the present time than formerly. According to my recollection they are lower now than they were in 1934.

I am not fully clear yet as to just what you mean by "rate of return." The rate of return as I have used the term in my testimony is lower now than in 1934, in my opinion. It is lower now than it was in 1929 or 1930. I think it is lower now than it was in 1915, 1916, and 1917, but that was a semi-depression period, and I am not completely sure of it. Of the three years last mentioned, 1917 was good, 1916 was medium. The country was in a moderate depression in 1914 and slowly recovered from it. It was well out of that depression by 1917. In 1916, there were as I say medium times, and somebody else might say pretty reasonably good times. I think rates of return today are lower than they were in 1916. According to my recollection they are lower generally now than they were in 1912. I am sure that interest was higher in 1912, but I am not sure that the equity rates were higher in 1912.

I understand that your questions have been directed at properties in the nature of public utilities. Where I refer to the interest rate and the equity rate I cover the annual compensation for the use of the capital. Generally there are some small items in addition, but that is the general explanation. By earnings available for equity money I mean earnings available for dividends. The comparisons I have been making were of established businesses with a history. I was directing my answers to public utilities or properties in the nature of public utilities, such as electric, gas, water, and telephone companies. Gas companies include both artificial and natural gas enterprises.

1213 In a broad sense, railroads, street cars, and buses would be so included, but in the last ten or fifteen years they have been classed as tractions, that is street cars and buses. Railroads are generally stated by themselves. My answers do not include these three types of industry but were directed to public utilities, covering principally electricity and gas. The gas companies include only distributing companies. I consider that a fair rate of return for defendant companies now would be less than I considered a fair rate of return for them to be five years ago. I made specific studies five years ago in respect to a fair rate of return for these companies, and I made specific studies today in preparation for my testimony in this proceeding with respect to a fair rate of return. I testified five years ago concerning a fair rate of return for these companies before a Special Master. In that connection I prepared certain underlying studies and exhibits which were introduced in evidence in that case. I do not understand that the defendants here were parties to that litigation. I did not appear as a witness for these defendants in that case.

I am not influenced by the fact that I am paid by the company in the testimony that I give. My testimony is the same that it would have been no matter who was retaining me on the subject of a fair rate of return for this company. The case in which I testified five years ago was Chicago District Pipeline Company versus Lindheimer and other members of the Illinois commission. I used, as I just stated, certain compilation of data, certain statistics, and arrived at a figure for rate of return by the process described in my testimony in that case. I considered the methods I then used to be the best then available. I thought they were sound, but I think we have better evidence today. I would consider that the methods used in 1934 for my testimony were sound today. I made some attempt to apply them here but not very seriously. I think we followed through with one method completely in the early part of 1938. That was the first method that I presented in the old case where we started with the rate of return on bonds. I do not remember the number of the exhibit we used in that case. We made no attempt to follow that method through in the preparation of our testimony in 1939 in this case.

I have appeared as a witness before the New Jersey Board of Public Utility Commissioners. That was in 1934. I have not appeared before them since then. I think the Chairman is still the same man. I don't know as to the others. I have a conception of the ordinary political meaning of "radical." I have heard that term applied to various regulatory bodies. If you mean by "radical commission" one that has made an effort to beat down public utilities, I do not think the New Jersey Commission is of that type. As I said, I am only familiar with the fact that the present Chairman is the same one that was in office in 1934. I do not know about the other members. The Commission, as it was constituted when I appeared before it in 1934, in my judgment was an emminently fair-minded commission.

I am acquainted with Mr. William Mulligan, Assistant Counsel for the Board of Transportation of New York City. He was counsel for the board before whom I testified in the Interborough Rapid Transit Company matter. That was last year. I consider Mr. Mulligan is a temperate and fair person.

1214 In my direct examination I covered and considered all of the hazards of the natural gas industry that I could discover after careful examination. I considered all of the hazards as I conceived them at the time I testified. In a general way I went into those hazards in my direct testimony. I described all of the bad features of a possible investment in the natural gas industry or in this company. I don't remember that I mentioned any advantages that the natural gas industry has over any other industry or that this company has over any other company or other types of company. This industry has some advantages by comparison with some other industries, and it has some advantages as an investment when compared with some other companies.

(Upon objection by Company counsel the Examiner refuses to allow Commission counsel to question the witness as to his intentions of presenting a complete and fair statement of the subject of rate of return in his direct testimony.)

It is certainly my intention to be fair to all parties concerned when I testify as to a fair rate of return. I so intended at the time I testified on direct examination.

I would like to call attention to the fact that I have not compared this company or this business with other businesses. I simply started with the actual results from 11 companies, representing in my opinion a fair cross section of the natural gas industry as applied particularly to production and transmission. I have testified on the subject of rate of return in other cases. I testified in what is known as the Dayton Case as to going concern value. That is the case that ultimately went to the Supreme Court and is reported in 292 U. S. I did not testify in the Columbus Case. Some testimony offered in that case was prepared generally under my direction. That testimony dealt with going concern value. It did not deal with rate of return.

I testified in the Logan Case before the Ohio Commission, but that was not within the 10-year period covered by the list which I sent in. I don't think I testified concerning rate of return in that case. I have not reviewed lately the cases in which I have testified on rate of return except as to those within the last ten years. I don't have any present recollection of testifying to rate of return in the Logan Case. I remember testifying on the subject of going concern value. I testified in the Chicago District Pipeline Company case on the subject of rate of return. I saw a copy of the Master's tentative or preliminary report, whichever it was, and the rate of return mentioned in that was considerably less than the rate that I testified to as my opinion.

I testified on the subject of going concern value in the Dayton Case, in which I testified that a separate allowance should be made for going concern value. I supervised the preparation of testimony and the presentation of the testimony in the Dayton Case on the subject of rate of return and also in the Columbus Case. In the latter case also the purport of the testimony on going concern value was that a separate allowance should be made for going concern value.

I testified on the subject of going concern value among other subjects in the Public Service of New Jersey case involving the electric rates of the Public Service Electric and Gas Company of New Jersey. The purport of my testimony there was that a separate allowance should be made for going concern value. I testified to the same effect before the New York Commission in the Syracuse Lighting Company case. In the Dayton and Columbus cases no separate allowance was made. I don't know what was the disposition of the Syracuse Case. In the New Jersey
1215 case the decision of the Commission gave a lump sum
covering both tangible and intangible property. The amount they fixed was less than the amount of reproduction cost new less depreciation plus undistributed construction overheads and before the addition of a separate allowance for going concern value. I did not testify to the cost of reproduction new. In that case we took the book figures of the investment in the property and trended them by

general accounts down to the then present time. I do not believe that could be called a reproduction cost new estimate. It produced an answer probably somewhat on the order of what a reproduction cost new estimate would have been. I did not testify to the reproduction cost in the Dayton and Columbus cases in which I testified as to going concern value.

I have not been previously aware of the New York Commission's opinion from which you quote, "No separate allowance will be made for the element of going concern value." I do not remember any statement by me in 1934 that the Northern Natural Gas Company was distinctly inferior as an investment to Natural Gas Pipeline Company of America; but I may very well have said that in 1934. It is my recollection that that distinctly was the case in 1934. I think it went through a reorganization, but I have not the details in mind. I think it is doing very well now. I have not had occasion to look into it, but it is my impression that it is doing about as well as this company. I have had no occasion to change my belief as to its status in 1934. To the best of my recollection the Northern Natural Gas Company was projected without large contracts in Minneapolis and St. Paul which they hoped to get, and the depression came along and left them in the lurch, so to speak. That was in 1933 and 1934, and I think it was reorganized. I cannot be positive about that, though. Since 1934 they have gotten contracts for St. Paul and Minneapolis. I have not made a detailed study of the comparative merits of Northern Natural and these companies as an investment. I don't know of any reason why it is not as good. I do not have the earnings statement in front of me. So far as I know, the Northern Natural is not superior to the defendants as an investment at this time. I cannot think of any reason why the Northern should be inferior to these companies at this time. The line is shorter and is run at conventional pressures of about 430 pounds. It is about 800 miles long, and its principal market is farther removed from the coal and oil fields, so that it is not subject to such a close competitive situation as the Chicago line. Its principal market is in Minneapolis and St. Paul.

It is not necessary for me to consult the document from which Mr. Slaff has read and which he says is a report of the testimony in the Public Service Electric and Gas Company of New Jersey case. I only would like to be sure that it is clear that that was not what is ordinarily called an estimated cost of reproduction new. Qualified as I have stated, it was called an estimate of the reproduction cost new of the property.

A sound capital structure for a natural gas company of the type of these companies would be, say, 50 per cent bonds, 25 per cent preferred stock, and 25 per cent common stock. I think the proportion of preferred stock would be too high if raised to 30 with a reduction of common stock to 20 per cent. It would not be as sound a financial structure as the one first suggested.

I have had no occasion to change my mind in the past year or two as to the propriety of providing a fund for
the amortization of an investment which has a limited
1216 life; and I think the sinking fund basis of computation is the preferable way to do it. I am not conscious of having changed my mind at all as to the method which I deem proper to use in determining what is a proper interest rate to be credited to such a sinking fund. It depends on the circumstances. I do not think I have in the past in my testimony indicated a method of arriving at the proper rate of interest to be credited to a sinking fund built up to amortize a limited life investment. There may have been some question of that kind involved in the Interborough tax case, but I don't remember. In the latter case the question centered around the value of the lease, which was principally represented by the annual earnings for a given period of years, and the problem was properly to discount those earnings. The only question of amortization that arose, as I remember, was the amount that should be deducted from year to year in the statement of income tax. The life of the investment was limited by the life of the contracts to operate the subways. In computing the present value I testified in that case as to the value as of the year 1912 of the contracts awarding the right to operate the subways. I think that was in effect testifying to the present value of a limited life investment. In arriving at that present value I deemed it necessary to provide out of earnings over the life of those contracts for the return of the purchase price at the expiration of the contract, as well as for the annual return. This contract conferred the right to operate the New York subways and covered only the original line.

The amortization to which I was testifying covered the investment which I thought a willing purchaser would make in that property as of 1912 if he had an opportunity to buy it from a willing seller. We were amortizing the investment over the life of the property or providing for its amortization during the continuance of that contract.

I think my testimony was given between two and three years ago. According to my recollection I testified to the language appearing on page 299 in the record of that case as follows: "In computing the present value of the future earnings to be used in the basis of purchase, it is necessary to provide out of the earnings for the return of the purchase price at the expiration of the contract as well as for the annual return thereon. This is computed by setting aside out of the earnings each year the amount that will accumulate with interest to equal the purchase price at the expiration of the contracts. I have estimated the rate of interest at which such fund can be expected to accumulate at 4 per cent per year, based upon the average yield of ten first class railroad bonds at December 31, 1912, which is 4.14 per cent."

I testified to the language you quote from page 5272 of the record in this case as to the experience of my firm in the natural gas business. The question to which that was the answer was not directed to me personally. I have not personally designed or constructed any lines. I have not personally participated in the financing or raising of necessary capital except insofar as consultations in the firm's offices have taken place regarding our participation. Personally I have had a very small part in that. I have joined in the discussion a great many times about it. I have never had any direct responsibility in connection with it. I have not had a great deal to do with the development of the market. I did some work along that line in connection with the Edmonton Company. I have done no actual work in the operation of gas lines and have personally
1217 done no marketing of natural gas. I was the general manager of an artificial gas company for four years.

In my testimony on page 5273 in which I answered: "To obtain the money necessary for the establishment of the enterprise it is necessary to hold out sufficient inducement. First, the safety and facility of conversion of the capital must be provided for, and second, an adequate rate of return," I was discussing in that connection either the rate of return necessary to interest investors in a hypothetical reproduction of the business or that necessary to attract capital from now on for such further financing as the business may find necessary. I make no distinction.

A man confronted with one or the other proposition will take everything into account when considering those propositions. I think that my answer would apply to either situation, and I was making no distinction. A different rate of return would be applied in one instance than in the other. An undeveloped enterprise requires a higher rate of return. As to how much higher, I would have to answer that question by giving a range. The money necessary for a new enterprise would require a rate of return dependent upon the degree of risk, and it might be anywhere from 3 to 10 or 15 per cent higher on the investment than that required for an established company. When I speak of three to ten per cent higher, I am speaking of per cent on investment as distinguished from per cent on the rate base.

I testified on direct that the natural gas industry, particularly when it includes production, is more risky than the average business. By average business in that connection I meant an investment list as you find in Moody's Manual, which list has been presented in the testimony here. In natural gas I was referring to the Public Utility Annual as one of those manuals. The Industrial Volume is another one of those manuals. I would not say that the natural gas industry is more risky than any business that you might find in any of those manuals. The natural gas production business is considered in the nature of an extractive industry. In my answers to the questions on direct, shown at page 5275 and 5276, I had no specific types of business in mind. (Testimony on hazardness of natural gas industry stricken on motion by Commission Counsel.) In my answer quoted from page 5276 in which I said in substance that when compared with an ordinary utility, such as an electric utility or other distributing utility or any type of continuing enterprise, there is more risk involved in the natural gas business, one of the considerations involved in that answer was that the natural gas business is not a continuing enterprise. It is my belief that the natural gas business is not a continuing enterprise.

The Hope Natural Gas Company has been in operation a great many years, since the beginning of this century, that is, it and its predecessor companies have been. Some of the subsidiaries of the Columbia Gas and Electric Company have been in business a great many years. I don't remember just how long the Columbia System as such has existed. That system operates largely in southern

Ohio and that general vicinity. It has a large subsidiary in western Pennsylvania and another one in West Virginia.

The Lone Star Gas Company system goes back as much as 15 or 20 years. I don't know that it goes back 30 years, as you say. The Lone Star Company itself was organized in 1926, and it acquired some gas companies which had been established quite a great many years before that, including the original Lone Star Company established in 1909. The Oklahoma Natural Gas Company goes back to 1933. The predecessor companies go back to about the turn of the century. All of the natural gas systems or enterprises that you have questioned me about in the last few minutes have been continuing along for the last 30 years or more on the average.

1218 I have testified on page 5277 that the pipeline company which owns its gas down in Texas and transports it to distant states like Illinois and sells it to distributing companies is confronted with the same risks as those confronting the distributing companies. If the distributing company has hazards, the pipeline company has them. If it is free from hazards, the pipeline company is free from such hazards. The more stable the distributing company, the more stable will be the pipeline company. A distributing company with a stable business would be more valuable to the pipeline company than an unstable distribution company. A pipeline company is concerned about the stability of the distributing company.

Referring to my testimony on page 5277 concerning the uncertainty of geologists' estimates, it is true, of course, that the error in estimate may be in one direction as well as in another. The geologist may underestimate the life of the field or the amount at the source of supply as well as overestimate. (Objection by Company Counsel overruled.) I think it is correct that the natural tendency of a geologist of a well-managed, conservative producing and transmitting company would be to underestimate rather than to overestimate the amount of supply. The reliable and well trained geologist will always take the conservative side. As a general rule, conservative and sound financing would require underestimating the amount of supply rather than overestimating it. You inquire whether with respect to operating revenues of such a company the same conservative and sound policy would require the underestimation of future revenues. (Objection by Company Counsel overruled.) I do not like to make such a sweeping answer as yes or no to the question. It is often the case that it is just as bad to make an underestimate as an overestimate, and I think in the case of revenues and operating expenses the practice would be to make those neither over nor under. As to the distinction I draw between the geologist and the man figuring operating expenses, I think my answer concerning the geologist was that I think a reliable man would take the conservative side. (Objection by Company Counsel overruled.) The distinction that I would make between the geologist and the revenue experience would be the difference in the quality of the evidence available. The geologist uses the best evidence that is available to him. A witness coming in here on a case like this would want to be sure of his ground, and I think that he would be inclined to overestimate the reserves.

Cross-Examination by Mr. Booth.

I testified in the proceeding known as the Chicago District Pipeline Company versus Lindheimer. I did not testify as to a proper rate of return for Chicago District Pipeline Company but merely as to the proper rate of return for the two pipelines here involved. I think I knew that in that proceeding there was evidence submitted by geologists as to the life of the reserves of Texoma Company in the Panhandle field. I have no definite recollection of it. I did not make any studies or examine estimates of the reserves of the Panhandle field or familiarize myself with such estimates. All I know about it is what I have been informed by the officials of these companies. They informed me merely as to the estimates which have been made in this proceeding. They did not tell me that the same geologists or any of them in the Chicago District Pipeline case testified that the life of the reserves were substantially shorter than they now testify in this proceeding before the Federal Power Commission. I made no inquiry as to whether or not the geologists who have testified in this case had made prior estimates indicating a shorter life than they now estimate.

Cross-Examination Resumed by Mr. Slaff.

The conservative side in making an estimate is sometimes higher and is sometimes less. That is, going before a banker I think the conservative side would be to
1219 underestimate, but for a proceeding like this I think
the conservative side would be to overestimate. You inquire whether I mean to say that a reputable geologist will express one opinion as to reserves to a banker, and a different opinion as to reserves to this Commission in dealing with exactly the same subject matter. (Objection by Company Counsel overruled.) This is a matter that cannot be determined to an exactitude. There is bound to be something of a range. In a case involving any uncertainty I think a geologist in making such an estimate would be apt to state a range. I certainly do not think that he would categorically make one statement in one place and a different statement in another; but I say that in any estimate provided, he would take the conservative side, whatever that might be. I do not think he would go out deliberately and give different answers with an intent to mislead in any way. In one case he might say "Not less than," and in another case he might say "Not more than." With respect to financing and with respect to the testimony in a rate proceeding, my judgment is that the only difference that a reputable geologist might make in the estimates which he would present in either case, referring to the same subject matter, would be to say in one case "There are not more than X number of feet, in my judgment," and in the other case "There are not less than X number of feet, in my judgment." I do not think that the natural tendency for an employee of a company estimating future operating revenues for financing purposes would be to deliberately overestimate or underestimate either. There is a field for judgment as to what the operating revenues will be, say 10 years from now. He cannot be precise at all at the present time in determining what the operating revenues will be 10 years from now. He cannot tell when he is prognosticating 10 years ahead whether he is going over or under. I would say that prognosticating 10 years ahead is more of a guess than if it were for only one year ahead. In a business of this kind I do not think you are in a field of pretty wide speculation when you are attempting to estimate 10 years ahead, if you assume a continuance of

present or known changes in conditions. The only basis on which estimates can be made up is on that of present conditions or known changes. I don't know and I would not predict today that such conditions will exist 5 years from now even. I would not predict as to what conditions will exist 10 years from now or in the range of 5 to 10 years from now. I would not predict today what conditions are going to exist 15 years from now or in the range of 10 to 15 years from now. An estimate respecting revenues 10 years from now is pretty much of a guess insofar as they are affected by changes in fundamental conditions. The same is true of operating expenses insofar as they are subject to change by radical changes in conditions. By radical I mean important changes in conditions.

I don't think a man in trying to estimate revenues and expenses for the future would attempt to prognosticate conditions or make any allowance for changes. (Objection by Company Counsel overruled.) The basis for the estimates of this company is a sound one now. They have had several years of more or less uniform experience behind them, and they know just what to expect under normal conditions. I am speaking about the estimates that might be made for this company; the estimates that Judge Morgan says I don't know about. I have not seen the future estimates for this company. I have seen some of these estimates that have been submitted as exhibits but I have not studied them. I would say that it is absolutely impossible to make in estimates any allowances for possible changes in conditions, and that estimates should always be predicated on a continuance of present conditions or known changes. An example of known changes would be the rise in the unemployment tax. What I have said with reference to present conditions or known changes applies to the operating expense estimates for the future mentioned a little while ago.

1220 I do not know what drafts the Texas Panhandle field is subject to for purposes other than pipeline purposes. I do not know what drafts it is subject to for other pipeline purposes. I do not know what drafts it is subject to for carbon black or gasoline stripping purposes. I don't know enough technically about the manufacture of carbon black to say whether sweet gas or sour gas is used in its manufacture. I don't know enough about the operations in that field to answer as to which type of gas is used for gasoline stripping. I understand that this field is subject to salt water intrusion, and I read Mr. Brown's testimony that it is. I am referring to Mr. Floyd Brown's testimony. All I know about it is what I read in Mr. Brown's testimony and what I have heard other people about the office say. Mr. Hill and Mr. Rhodes of our office are familiar with that field. Mr. Rhodes is one of the vice presidents of our company. The basis of my knowledge depends on my reading of the testimony of Floyd C. Brown and the discussions I have had with Mr. Hill and Mr. Rhodes of our organization.

What I know about the migration of sour gas into the sweet gas areas of the Panhandle is based on the same sources. I cannot name the specific discussion of these subjects; but it is one of the matters that have been talked about at different times in my hearing. I know nothing specifically about the migration of gas from the sour to the sweet areas except what is contained in Mr. Brown's testimony.. I know nothing about whether the intrusion of salt water in the Panhandle is from above or below the gas producing areas. I know nothing about the predictions that have been made with respect to future drafts on the field. I am in no position, therefore, to state whether the company witnesses in this case have underestimated or overestimated drafts for the future. I have made no effort to ascertain what the company's estimates of future drafts have been. I know nothing beyond the estimated future life of the field that has been presented here in the testimony. I do not know what the withdrawals from the field have been in the last five years, the last ten years, or during any given period in the life of that field, or how such withdrawals compare with the withdrawals in any other given period.

I testified as shown on page 5278 of the record that the fact that another pipeline should be built or that other carbon black industries should enter the field and utilize sour gas for the manufacture of carbon black would tend to limit or reduce the amount of gas available for this company. In answer to your question whether that will necessarily follow I cannot say any more than that would intend to. It is a matter of common judgment that if more people use it, it will be exhausted sooner.

I know nothing about the migration of gas from one part of that field to another. I know that gas migrates and that migration in that field is considered to be rather greater than in the average porous field, so I would think that if one man drew gas from one part, the gas from the other part would tend to migrate to it. I mean it would migrate.

I do not know anything about the Texoma Natural Gas Company reserves in the field. I do not know anything about the Texoma Company's requirements for the next five years, except insofar as what the sales are now and the expectation of continuing them for the next five years are concerned. I think the entry of another pipeline into the Panhandle field would shorten the life of these 1221 companies. I cannot say how much. That would depend on the size of it and the amount of the draft, but naturally, if any one else comes in there and takes gas, less gas will be left. There would be a migration from Texoma's reserves. I do not know how Texoma's reserves today compare with Texoma's requirements for the next 15 or 20 years, except that I understand that their resources are estimated to be sufficient to supply them for that period. I have no hesitation in saying categorically that the entry of another pipeline into the field would shorten the life of this company, regardless of the size of the pipeline. Naturally, it might shorten it five minutes or it might shorten it five years, depending on the size. Regardless of the size of the pipeline, the entry of another pipeline into this field in my judgment would shorten the life of this company. I am not speaking generally but specifically. I want to make it clear, however, that a very short time, such as five minutes, would not be worth talking about. Anything I talked about in connection with shortening the life of the field is something worth talking about. When I testified that if another pipeline should be built into the field it would shorten the life of the field, I meant that it would shorten it enough so that it would be noticeable. I assumed to testify categorically on that subject without any more knowledge of the field and the geology of the field than I have indicated.

When I testified as shown at pages 5279 and 5280 in effect that assuming that the market is always available and favorable, or the estimates are made altogether under favorable circumstances, it is almost certain that in a term of years there will be some circumstances not favorable, I meant that the estimates would have to be based on the assumption that no conditions essentially different from those at present or now foreseen would occur. When I testified that the providing of an annual reserve for amortization over the indicated life of the field would not remove the hazard involved in the question of whether or not the capital of these investors will be returned, I assumed that the entire capital investment is to be amortized over the remaining life of the Panhandle field. That would be the estimated period of 16 or 20 years or whatever it was. When I testified as shown by the record at page 5280 that if the funds provided for the return of the capital be distributed over the entire indicated life of the field, an investor would consider that his investment was still subject to hazard, I meant that he could not count definitely on all conditions being favorable.

You asked if he might not consider that the capital would be returned at the end of the period provided for amortization and the business still continue. (Objection by Company Counsel overruled.) That is a contingency that he certainly could not bank on, and it would be a pretty long gamble. He could not bank on the field's going out before the indicated life. He cannot get back funds by banking on any contingency. You cannot bank on any contingency such as the field going out before the indicated life. I was testifying at the top of page 5281 about what an investor would consider. He might consider that the capital he invested would be returned at the end of the period provided for amortization and that the business might still continue. I think that he would be inclined to rule that out as a factor because it is such a long gamble.

With respect to the report of the geologists looking 16 years ahead, I should call that a long gamble. I have not read the reports of any other geologists, and I am basing my judgment on the reports of geologists in this case that have been produced by the company. If an investor considered that the field may last longer than the period provided for amortization and that his capital will be returned at the end of the period provided for amortization, that, in his judgment, would be a favorable circum-
1222 stance insofar as it is a possibility. I think, however, the investor is more inclined to study the unfavorable side because the hazards are on that side. I would say that he studies the favorable side less diligently than the unfavorable side. As to your question of whether he comes to a balanced judgment, in my mind by studying one side of the picture my answer is that it is the customary way to study hazards. In that observation I mean the investor. The foundation of my direct testimony was the investor's

appraisal of natural gas securities as evidenced by the price and earnings. That, I think, is a direct illustration and final answer as to what the investor thinks.

When I was discussing in my testimony the fair rate of return that an investor would demand or want or have to have to be satisfied and to meet all of the conditions of fairness, I did not assume that the investor looked just at the dark side of the picture of the prospective investment. He looks at both sides, but as I said before, I think he gives more thought to the unfavorable circumstances. He tries to take the greatest care possible not to get hurt. He is primarily interested in not getting hurt. I think he gives more consideration to the unfavorable circumstances than to the favorable ones and that these influence him more than the favorable circumstances. It was that type of investor that I had in mind in my direct testimony, and it was that type of investor I had in mind when in answer to the question: "How would that affect the rate of return which he would expect from his investment under those conditions?" I said: "That makes the required rate of return to attract the capital higher," as appears at the top of page 5281. I meant that it would be higher than it would be if there were not such a hazard. If I were asked a question, as you suggest, "In view of the fact that you say that these estimates always are attended by uncertainty, the field might last a year or two longer than 16 instead of playing out or becoming exhausted one or two years short of that period, does that remove the hazard?" I would answer that it does not remove it. It does not minimize the hazard or lessen the hazard because that contingency is always present. I have testified on the direct that the fact that it might last a few years longer would not remove the hazard. I do not think that such possibility would lessen the hazard at all. If there is a possibility that it may last less than 16 years, it does not make any difference if there is a possibility of its lasting 20 years after that, for that does not take away the hazard of its lasting 16 years.

My difficulty in answering comes in trying to evaluate a gamble beyond 16 years. (Objection by Company Counsel overruled.) As to whether the importance of that hazard in the investor's mind is lessened by the fact that the field might last five years more, I believe an investor would say that he has to guard against a hazard and that if the field should run over that length of time it would be just a matter of luck, but that he would not assign any value to that element. If in the light of the circumstances there was a reasonable probability in the inventor's mind that the field would last longer than the period indicated for the amortization of his investment, I still do not think it would lessen the hazard, but the reasonable probability would have some value. If you should match that reasonable probability against the hazard, it would lessen the significance that the hazard played in his own mind.

(October 24, 1939)

An investor investing his money in this company in 1930 is entitled to have his investment amortized over the life of the field. In 1930 I think an investor would expect his investment to be amortized over the life of the field, whatever that might be, not necessarily at the same rate continuously. His investment in 1939 should be
1223 amortized over the remaining life of the field. By his investment in 1939 I mean what he has in it. I mean the present value of the property.

Question by the Examiner.

In appraising risks as of today with respect to any concern that had a past life and which, during that past life, has earned enough to set up an amortization reserve during that past life, in appraising the risk of a going concern like that I do not think in the case of an unregulated industry that I would take into account that its earnings had been favorable in the past, and I did not do so in this case.

Cross-Examination Resumed by Mr. Staff.

In stating that the investor in 1930 should have his investment amortized over the life of the property, whatever that life may be, I meant that he would expect to get his money back when the life of the field expires. If there were no rate inquiry directed against these companies until the year 1949, and if there was geological testimony introduced by company witnesses in that rate proceeding in that year that the life of the field would be exhausted by 1954, I think the Federal Power Commission in setting up rates should provide for the amortization of the value of the property at that time, whatever it is found to be. In answer to your question whether I am distinguishing between "value" and "investment in the property", I think the investment in 1930 was what was put into the property. I think the investment now is represented by its value. (Objection by Company Counsel overruled.)

(The following question was asked the witness by Commission Counsel: Q. Now, assume, Mr. Emory, that there is a rate case in 1949, the first rate case this company is involved in under the Natural Gas Act, which then exists as it exists today and evidence is presented by the company of its investment in the company; evidence is also presented at that time by the company of the reproduction cost of the company as it then envisions it do you say that either the reproduction cost or the investment should be amortized over the period 1949 to 1954 and the fund to provide that amortization should be built up over that period, that 5-year period?) (Objection by Company Counsel overruled.) May I explain as a reason for taking so much time to get the question through my head and for having it read over, that it is such an academic and impossible one that it is difficult to visualize it. If the whole investment were intact in 1949, it would be practically impossible to amortize it. That is, this company is within very strict limits as to the price it can get for its products. I still cannot say anything more than that the value, whatever it is found to be in 1949, would have to be amortized or should be amortized in the succeeding five years. By "if the whole investment were intact in 1949" I meant by investment the value found in 1939. In my view, value and investment would become the same when regulation goes into effect. (Objection by Company Counsel overruled.)

When in response to a question at the top of page 5282 reading, "If it runs longer than expected, the situation must be dealt with according to conditions at that time," I answered in the affirmative, I meant that it must be dealt with by the regulating body. In answer to your question as to whether I meant that if the investment were amortized over the estimated life of the field, and it then turned out that the life of the field still continued, the regulatory body could rule by order that the investor having had his capital returned to him, was no longer entitled to a return on the property or on the value of the property, or on his original investment in the property; my answer is that it is my understanding that the Federal Power Commission or the regulatory body would have power to do anything it saw fit. (Objection by Company

Counsel overruled.) My conception of what it could do under the circumstances I have just stated is that it would find a reasonable return on the fair value at that time, whatever that might be. I do not know that the Federal Power Commission cannot do anything it sees fit to do. I understand that its powers are to impose what it considers a reasonable return on the fair value. In answer to your question as to when at the end of the estimated life of the field the investor has his investment completely returned to him and the business of the company still continues, it is my conception that this Commission should then fix the fair value of the property and allow the company a fair return upon that fair value and that that was what I had in mind in my statement that the regulating body would protect the public if it developed later that there had been an estimation of the life of the field. I would not attempt to say what the Commission should do. The Commission would protect the public by finding what they consider a fair value. I understand that is wherein the public protection exists, in confining the company to a reasonable return on the fair value, and, in company operations, by prescribing the accounting regulations. It would protect the public with respect to the underestimation of the life of the field through its finding of value.
1224 As to how the public at that time would be protected against the underestimation of the life of the field that had been made previously, I think the conditions at that time, and the history after regulation went into effect would control. I had nothing specific in mind except that the Commission would hold the company to a reasonable return on the fair value. If the entire value had been amortized, there would be no further provision for amortization. The investor, once having had the value of the property amortized and returned to him and having received a fair return during that period on the value of that property, would from that point on be entitled to a return upon whatever value might be found in the property then, for the rest of the property's life.

Referring to the question at page 5282 in which I was asked: "Why cannot the Federal Power Commission, if we make it specific, protect the investors in defendants against losing a part of their capital due to the lives being shorter than that indicated by the testimony under the most favorable conditions?" and my answer: "Principally because their business is all highly competitive, and

~~even~~ if they were permitted to charge higher rates, they could not get them," I based the answer on the fact that all of the business of this company has been obtained on the competitive basis by underbidding other people, by underbidding other fuels, and if they raise their rates they will take themselves out of the market.

You ask if that means that they are now charging as rates all the traffic will bear; I certainly would not express it in that way; that is not what it means. (Objection by Company Counsel overruled.) That expression is generally used in connection with a more or less non-competitive business where it is a question between the volume of traffic you can get and the rate. Yes, I have heard that expression used in connection with railroads. I certainly would never express myself in that way, but the meaning and the fact are that there are competitive fuels in the Chicago market. This company to get its business had to bid under them. If it raised its prices and they did not raise theirs, it could not get the business. Practically, I didn't consider that there was any margin wherein the company could raise their rates between I feel that they are charging today as much as they can because of the competitive situation. I do not understand that that expression "all the traffic will bear" would apply to charging what they can under the competitive situation.

In my answer shown on page 5283 of the record, "I should think with this company operating in several states, and also under Federal regulation, it would have to expect more than one," I meant that defendants would probably have more than one rate case on their hands. I was assuming that the rate would be the same at that future time as it now is. I understand that the rates of this company are subject to state regulation. As to whether it is my understanding that the Illinois Commerce Commission can regulate the rates of Natural Gas Pipeline Company of America, I consider it practically the same thing, that is—that they could regulate the rates of the principal user. When I was retained to make a study of the rate of return for these defendants, there was a proceeding before the Illinois Commere Commission. I, of course, know little or nothing about the law in this matter, the interpretation of the law; but my statement in the direct testimony was made with the understanding that the Illinois Commerce Commission did have or claimed to have some regulatory or investigatory authority over defendants. As far as my knowledge goes, the Illinois Commerce Commission has no power to regulate the rates of defendants today. I should suppose under those conditions that there could not be a rate case before the Illinois Commerce Commission covering this company alone. The same would apply to every single state in which the company operates.

Redirect Examination Interposed by Mr. Morgan.

From the standpoint of an investor, I do not see that there would be any difference in a rate case conducted before the Illinois Commerce Commission and one instituted by it before the Federal Power Commission. I see no difference in a proceeding pending before the proper commission in Iowa, Nebraska, Kansas, and the one
1225 which they might separately institute before the
Federal Power Commission. There could be just as many rate cases on the complaint of the various states as if they had jurisdiction themselves.

Cross-Examination Resumed by Mr. Slaff.

In my testimony I was considering the possibility of the rates being raised. I do not understand that the Natural Gas Pipeline Company would have to go to other than the Federal Power Commission to get its rates raised. On page 5283 I testified that there would be a rate case in the Federal Power Commission and every one of our distributors would have to go and get its rate increased in order to meet the increased price which the Federal Power Commission might provide. I do not know much about the earnings of the distributors who purchase gas from these companies, nor do I know anything about the proper fair rate base or the proper operating expenses or the fair rate of return applicable to any of such distributors, except that I know generally about the rate of return that would be required on the average for such companies. I would not state now, nor would I have stated on my direct testimony what was a fair rate of return for any specific distributor of Natural Gas Pipeline Company of America. (Objection by Company Counsel overruled.) I do not know all the specific facts relating to any of these companies, and such information as I have is to the effect that generally gas distributing companies are not making more than a fair return because most gas distributing companies are not making a fair return. The competitive situation has exerted such a pressure on them that they have not been able to meet it. I do not have specific information in respect of whether any of these distributors of Natural Gas Pipeline Company of America is today making more than a fair return, so that it could absorb an increase in rates of Natural Gas Pipeline Company of America, such as I was discussing in my answer at page 5293.

A company does not apply to increase its rates every time its operating expenses go up nor does it apply to decreasing its rates every time its operating expenses go down. Operating expenses might go up or down by a small amount without any adjustment in the rates; but if they go up or down by a very large amount, there would have to be some adjustment in the rates. I do not know what proportion of the operating expenses of any of the distributors of Natural Gas Pipeline Company of America is represented by the amount it pays defendants for gas. If we assume that a distributor must have its rates increased, I do not know of any cases of rate increases without a rate case. I do not personally know of any increase in rates without a rate case since regulation came into effect. I made no attempt to find out about any. I therefore do not know about the number of schedules, if any, embodying increases that may be filed with various commissions during the course of a year. I understand that when the Peoples Gas Light and Coke Company applied for an increased rate in Chicago there was a rate case brought against them. (Motion to strike above testimony by Commission counsel denied.) I used that expression, if I may explain, to cover all cases, whether the commission took action to prevent the company from making such a raise or some outside person or body did so. I did not know the exact circumstances, and that is the reason that I said that I understood the facts to be as stated.

By my testimony shown on page 5284 of the record to the effect that while the company has undertaken to predict the cost of additional wells which they can now foresee and the cost of providing field compression necessary to get the gas from the wells into the main line, and has brought in figures showing the minimum costs incident to the drilling of such wells and the boosting of gas into the line, the figures if incorporated in the rate base would not remove the hazard because if they brought in a minimum estimate of cost it could not be expected that all condi-

tions will be favorable for 16 years, I meant the cost as estimated by the witnesses referred to in the question. By the use of the expression "minimum" in the question asked me at that time, I understood the meaning to be the estimated cost without provision for possible changes in
conditions which would tend to increase the cost.
1226 (Objection by Company Counsel overruled.) I did
not understand that there was any provision made for changes which might tend to decrease the cost. I have seen the figures brought in through these estimates, but I have not memorized them or analyzed them. I have every reason to think they are reasonable estimates, but I do not know what they amount to. I have made no study to determine for my independent judgment whether they are fair or unfair. I do not know whether these figures were increased in the record by an allowance by another witness for contingencies. I do not remember having testified about allowances for contingencies in my original testimony, but I see here that it was mentioned in the record. However, I do not think that the allowance of that 10 per cent would change my answer, because in the course of 16 years I think the contingencies and hazards relating to operating expenses would be more than 10 per cent. I would not attempt to appraise or set a definite figure that I think would make allowance for such contingencies in operating expenses.

I am not intimately familiar with the tentative system of accounts prescribed by the Federal Power Commission for natural gas companies. I do not think that I would say that I am generally familiar with it. I have heard it discussed, but I am not an accountant and know very little about that. I have not looked at it. I am not familiar at all with the system of accounts for natural gas companies recommended by the National Association of Railroad and Public Utility Commissioners. A number of years ago I made a study of a system of accounts proposed to be promulgated by the New York Public Service Commission covering artificial gas companies, and I don't remember just what other authorities I consulted in the course of that study. I know of no system of accounts prescribed by any Federal regulatory body or state regulatory body which does not include maintenance expense as an operating expense. That applies to all types of utilities and regulated companies. I think it is correct to say that in all such prescribed systems of accounts maintenance is included as an operating expense.

Referring to my testimony at page 5288 concerning the pressure and stress at which this line is operated, what I call conventional stressing runs about 12,000 to 15,000 pounds per square inch. I do not know of any major pipeline that has been built to operate at higher pressures than this line. I do not know of any line built to operate at 1500 pounds pressure. I attempt to keep up with developments in the field. I attempted to make an investigation prior to my testimony here as to pressures at which other lines were being operated, higher pressures as well as lower pressures. I consulted the records in our office and consulted with various natural gas engineers in our office and with officials of defendants. We get Gas Age down at our place. I know Thomas R. Weymouth. I don't know his exact title, but he is a high natural gas official of Columbia Gas and Electric Company. He is also chairman of the Natural Gas Section of the American Gas Association. I do not know anything about the line referred to in the January 1939 issue of Gas Age in which Mr. Weymouth described a development in the pipeline industry as follows: "Another development during 1938 has been the testing out of lines of extremely high pressure. One in particular is a 12-inch line built for ultimate operation at 1500 pounds, but which up to this time has been operated only to a pressure of 1300 pounds."

1227 Pipelines are normally subjected to stresses up to in round numbers 40 per cent of the elastic limit. The Southern Natural Gas Company operates at a stress of 15,000 pounds per square inch, which is approximately 40 per cent of the elastic limit of the steel. The Interstate Pipeline Company, the Colorado Interstate, and the Mississippi River Fuel pipelines are all operated in round figures at 35 per cent of the elastic limit.

The final rate of return figure that I presented here of 9 to 10 per cent includes a consideration of the pioneering skill which this company exercised in three particulars, one of which was the operation at these high stresses. Not only the skill and vigilance of the operating organization was considered, but of the designers and the enterprise of the investors in putting up their money on such a basis. Yes, I did mean that my rate of return included an element of compensation for the vigilance and skill on the part of the operating organization to which I referred at page 5288.

Yes, consumers pay the money which provides for the operating expenses. Of course, the company pays the operating expenses. I really don't know how I can answer that any differently or any more clearly. The consumer pays a rate which is supposed to cover the return and the operating expenses, and the company pays the operating expenses. I have no doubt that in the Public Service Electric case in New Jersey in reply to a question shown at page 3221 I said that assuming a period of years when the company does earn a fair return in effect charges to operating expenses are borne and are paid by the consumer. It is a fact that assuming that the company is earning a fair return, charges to operating expenses are in effect borne and paid by the consumers. The consumers, of course, are the source of the funds from which the company makes its payments. In the same way the salaries of officials and employees of a utility company are paid by the consumers under the same assumption that the company is making a fair return. Generally all such charges are charges to operating expenses. The reason I say generally is that sometimes there are stock options or the privilege of subscriptions offered to officials. All salaries or parts of salaries resulting from operations are charged to operations, as far as I know. The reason I say parts of salaries is that there may be some portions of some of the salaries charged to construction account. Such portion goes into the fixed capital accounts as overhead charges. Operating expenses and charges to operating expense are something entirely separate and distinct from the return or from the rate of return.

In my going concern testimony in this case I testified that the operating organization, skilled and trained as it was, added an element of value to the property over and above the value that the property would have without that organization. In my judgment and according to my testimony the company should receive a return on its going concern value as well as on the other elements that I conceived to go into the value of the company. (Objection by Company Counsel overruled.) It is not according to my rate making concept that the investor is entitled, in addition to the capital value placed on a skilled organization and a return on it, to a further increment of return on the entire rate base because of that skilled organization. Generally I do think that a company is entitled to include in the capital value some value for skilled organization

and that it is entitled to receive a return on that element of capital value. I have not said that it is also entitled to include as an increment or element of its fair rate of return, the fact that it has a skilled and vigilant operating organization. That is true only when extraordinary or outstanding developments have been made. I do not
1228 remember that I have ever testified in a rate case in
which I did not testify that the company involved had a skilled operating organization and that that was one of the elements I considered in coming to my conclusion as to the rate of return. I have generally treated the assemblage and training of the organization as an element of value on which the company should be entitled to earn a return, but I have not done so in this case. In this case I did not treat the operating operation and skill as an element of value.

I testified as shown on the record at page 5290 that the possibility of exceeding the elastic limit of the line was a hazard and that the immediate result of exceeding it would be the expense of repairs and the interruption of business, but that if it became necessary to reduce the pressures, it would substantially reduce the earnings. That was one of the hazards I envisioned as being in the investor's mind. This line was designed and intended to operate under the conditions under which it is operating. It was not so intended at the beginning. The operating pressures were raised a few years ago. The design and building of the line was due to the initiative and skill of the originators of the line, the entrepreneurs and their agents. I proposed in my direct testimony that they should be compensated in full for that skill and initiative. If it should develop that the uses to which the line is put so exceed the elastic limits of the line as to cause any failure due to the high stresses, that would not imply any discredit whatever on the builders of the line. This was an entirely new procedure, and they showed great enterprise in going into it. No new thing of this kind can be designed with 100 per cent perfection.

I understood the question on page 5290 to refer to difficulties resulting from high stresses. I would like to add to my answer that the possible deterioration in the pipe and equipment must be considered. In exercising their skill and initiative in the original design and building of this plant, the owners doubtless took into consideration the possible deterioration of the pipe under the pressures at which it was worked. I cannot directly answer your question as to whether, should the contingency occur, to which I referred in my testimony at page 5290, it would turn such great skill and initiative which I say the displayed was perhaps not as I now conceive it to be. The results so far have been satisfactory. You inquired if it should turn out that over the next 15 years the results should not be so satisfactory as they contemplated, whether or not it would not show that their skill in projecting the enterprise as they did was not as I conceive it to be. That is too general a statement for me to subscribe to. I think they showed remarkable skill and enterprise in what they have done. Of course, what they have done is subject to conditions or hazards that may turn up in the future, but whatever they turn out to be does not detract from the initial skill and enterprise. The measure of the value of the skill is in the success of the skill. I cannot subscribe to your suggestion that if what we conceive to be skillful or skillfully done today turns out to be a failure sometime in the future, that such skill would not have the actual value we placed on it. Hazards entirely unlooked for or changes in conditions entirely unlooked for might arise. If it should turn out that say next year pressures would have to be reduced on this line, less gas could be transported; earnings would be less, and I would say that the skill of the enterprisers in this case was less than I had conceived it to be when, in October, 1939, I testified in this case about that skill. I would say that the value of it is less or that the consideration should be given to it is less. (Objection by Company Counsel overruled.)

In connection with my Exhibit 149 and my testimony in connection with it, I included in my rate of return an element in the fact that the earnings of this line, operated at 750 pounds or thereabouts, are greater than the earnings
1229 of the line would be if it were operated at a lower pressure. Among the hazards I considered in connection with a proper rate of return for defendants is the possibility that the earnings of this line may be reduced through a necessity of reducing the operating pressures below those now maintained.

When I spoke at page 5294 of the record of the fact that I had organized and for about six months was in charge of a valuation of the East Ohio Gas Company, Peoples Gas Company, and the Hope Natural Gas Company, I was referring to work I did in a rate case. Those companies are so-called Standard Oil Company affiliates. My firm and I do considerable work for the Standard Oil and its affiliated companies. The Standard Oil of New Jersey is one of the large owners of Natural Gas Pipeline Company of America. That company owns 13.31% of the stock. Our firm is now doing a job in connection with the Colorado Interstate in a rate proceeding. It also is a Standard Oil affiliate or subsidiary. We are also doing a job in connection with a rate investigation involving the Hope Natural Gas Company.

It is true that at page 5295 of the record I stated that for the past twenty years I have been more or less intimately connected with natural gas matters, that this had been one of the activities of the office, and that financing matters are almost always discussed among us. I am somewhat familiar with matters involving the financing of the Southern Natural Gas Company. I know that that company has outstanding a loan of $1,500,000 by a bank. My Exhibit 148 shows it to be $1,489,000 as of December 31, 1938. The interest rate on that loan was 4½ per cent. I do not know that the rate is 4 per cent today. This information was as of December 31, 1938. I don't know what bank holds that loan or where the bank that holds that loan is located. I do not know anything about that loan or its status today. I don't believe I have had any discussion with any one in my firm respecting that loan in the past month or two. I came back from my vacation early in September. No one has discussed the Southern Natural with me during the past six weeks. I have discussed the Southern Natural in the past with Mr. Von Puhl and Mr. Hill. I have stated that Mr. Von Puhl is a member of the Board of Directors of Southern Natural and that he is a member of my firm. He did not inform me that the interest rate on that bank loan had been reduced in July, 1939, from 4½ per cent to 4 per cent. I don't think I said I was intimately connected with the details of financing and financial matters around my firm. I said, "Financing matters are almost always discussed among us." I don't know whether this particular transaction was discussed in the office or not. I was out of the office in July. I am not familiar with this or that Southern Natural has pending before the S. E. C. now an application for a declamation involving a reduction of the interest on this bank loan from 4½ per cent to 4 per cent. I do not know that there is such an application pending. I have not heard of it. I have not heard at all since my return that Southern Natural was before the S. E. C. in connection with anything. I left on my vacation early in July. I had no intimation about my office prior to leaving on vacation that any attempt was being made to procure the lower rate on the Southern Natural's bank loan. There was no such discussion to my recollection.

(At this point counsel produced a letter with the request that it be marked for identification. At the direction of the Examiner it was marked Exhibit 153 for identification.)

1230 I have examined Exhibit 153. I never saw that letter. It is dated July 13. Before coming to the stand on my direct testimony I sought to find out the status of the companies listed in my Exhibit 148 at June 30, 1939. Answering your inquiry if I had a check made with respect to the Southern National Bank loan as of June 30, 1939, I had similar information prepared as far as we could do so as of June 30 of such of these companies as we could get information on. Mr. Timberlake had charge of it. Mr. McKenlon made the study. If there was an intimation to Southern Natural and the members of its Board of Directors at June 30, 1939, that there was a reduction in the interest rate of the bank loan contemplated, I did not know about it. As far as we could ascertain from the public records, this fact was not disclosed. It was our endeavor to get all the information possible. With respect to the status of these companies I don't know whether I instructed Mr. Timberlick to confine his investigations to the published records or whether I told him to get his information from the June 30, 1939. I am somewhat familiar with financing utility companies and business companies and corporations in general. Usually the reductions in interest rates from banks are the subject of negotiation. I do not know that this situation involving the Southern Natural was in any way unusual in that respect.

Referring to my testimony on page 5296 to the effect that in connection with this testimony we consulted with engineers as to the operating characteristics of this pipeline or similar pipelines, and to my testimony a few pages thereafter and your question as to whether all of my information was second-hand or third-hand, I don't know just what you mean by second-hand or third-hand. If you mean that if I had this knowledge myself that would be first-hand, and that if I acquired it from somebody else who had the knowledge it would be second-hand, then it was second-hand. I certainly did not intend to testify right along, before the point was raised, in the record, as though that was first-hand information of mine. I was asked to cite the experience of the firm. I do not understand that in my discussion of the hazards of this pipeline, physical hazards and mechanical hazards, I testified right along as though that was first-hand knowledge of mine with respect to those hazards. I don't believe that I was asked if it was first-hand of my own knowledge. I certainly did not intend to imply in any way, shape, or fashion that it was my personal experience.

(Reference to transcript from another proceeding read into record by Counsel for the Commission for the purpose of impeaching the credibility of the witness struck from record on motion by company counsel. The following questions and answers were also stricken by the Examiner:

By Mr. Slaff:

Q. Now, I ask you whether in the Public Service of New Jersey case when we were discussing—you and I in the cross-examination—hourly wage rates, wage rates for different classes of workers which were obtained by you or your organization through the office of the United Engineers and Constructors, and which you had testified on the direct, whether you were not asked this question and whether you did not make this answer:

"Question (By Commissioner Reardon): According to your testimony, you don't know anything about it?

"Answer: Yes.

"Question: That is the fact, isn't it?

"Answer: Yes, that is right.

"Commissioner Bachrach: You mean the testimony today?

"Commissioner Reardon: Yes."

Do you remember that being asked you and your making those answers?

Mr. Morgan: We object to it.

The Trial Examiner: I will let it stand until I see what counsel is going to do with it. Answer the question.

The Witness: No.

By Mr. Slaff:

Q. You do not deny, of course, that that did occur? All of that colloquy did occur between Commissioner Reardon and yourself?

A. I cannot deny it.

Q. And if it appears in the record of that case, it did occur?

Mr. Culton: That is argumentative and we object to it on that ground.

The Trial Examiner: I will let him proceed.

The Witness: Yes.)

At page 5301 of the record it appears I testified with respect to various hazards, mechanical and physical hazards, of these companies. I think a fair rate of return for this company would be higher than for a telephone company. Telephone companies have some of the same kind of hazards that these companies have. I think their river crossings are more generally on bridges. I do not know how many rivers the Illinois Bell crosses throughout the State of Illinois. I do not know how many river crossings there are for telephone companies between Texas and Chicago. I know nothing specific about the danger of damage to telephone company equipment by floods. They encounter hazard from such things. Electric operating companies encounter hazards from weather conditions. The troubles they have with floods are more largely power houses located in flood districts. Some other public utilities have such hazards. I don't know specifically about the flood hazard of the Louisville Gas and Electric Company in 1937 or about the flood damage to that company in the 1937 floods. I know nothing specifically about the damage to the Cincinnati Gas and Electric in the 1937 flood. I know there was a flood down in the Ohio Valley at Cincinnati and Louisville in 1937. It was a pretty bad flood. I heard a good deal about the damage in Pittsburgh.

1231 The hazard of floods is not unique to natural gas transmission companies but is generally considered to be somewhat greater in degree. I said at page 5301 of the record that this hazard is very important because it entails a good deal of money for repair and loss of business during repair. Yes, insofar as such losses entail additions to fixed capital, those additions are entitled to enter into the rate base; and the company is entitled to a fair return thereon. Insofar as such expense is chargeable to maintenance, it is a proper charge to operating expense over and above which the company is entitled to earn a fair return. I made the statement quoted by you from page 5301 of the record concerning the other hazards applicable to the business of these two companies.

I know Percy S. Young. He is vice president in charge of finance of Public Service Corporation of New Jersey. He holds a similar position with a subsidiary of that company, Public Service Electric and Gas Company of New Jersey. He was formerly president of the American Gas Association. I have considerable confidence in Mr. Young's statements as to facts and his expressions of opinion. (Objection by Company Counsel overruled.) I was not aware of the article by Mr. Young entitled "Investment Attributes of Gas Utility Securities" presented May 15 in San Francisco at the Executive Conference of the American Gas Association, in which he discussed the merits of the modern gas range as follows: "1. Cooking. The modern gas range is a remarkable achievement. It is more efficient, excels and out-performs any of its competitors. Public acceptance has been immediate any enthusiastic. The modern gas range has placed gas in a preeminent position in household economy. During the year 1938, over 1,000,000 new gas ranges were sold." I was aware that there were large sales of gas ranges in the year 1938. I did not know that Mr. Young said that: "2. Water Heating. This field offers one of the greatest opportunities for expansion for a highly desirable log. Lower initial costs and substantial improvements in efficiencies have met customary requirements and public acceptance has followed. Sales of 47,000 water heaters in 1938 exceeded previous year's sales, while the sale of many non-gas-using major home appliances showed more decreases." I was not familiar with the facts thus summarized by Mr. Young. I did not know about the number of gas heaters that were sold in 1938, and I made no effort to find out the number sold or to compare the number sold that year with the number sold in other years. I did not know that Mr. Young in the same address went on with the summarization: "3. Refrigeration. Gas refrigerators continue their extraordinary public acceptance and relative sales results were better than other types of automatic refrigerators during 1938." I was not familiar with the fact that Mr. Young made that summarization. All I can say to that is that gas refrigeration is quite a minor portion of the gas load; and it might very well be that the percentage of increase in gas refrigeration apparatus was higher than the percentage of increase in electric refrigeration apparatus. I don't know that the absolute sales for gas refrigerators exceeded the previous year's sales, but I should think that is reasonable. I did not know that Mr. Young had made the statement that: "4. House Heating. Faced with keen competition, gas house heating has made outstanding gains. Manufactured gas sales for residential house heating increased every year throughout the depression, and throughout 1938 were almost four times the 1929 sales. Gas house heating entrenches the other three services of cooking, water heating, and refrigeration." (Objection by Company Counsel overruled.)

Questions by the Examiner.

I am aware that gas house heating has done pretty well, but it is my opinion that it lags behind the use of oil. It is certainly true that the gas companies are faced with keen competition and that there were outstanding gains. I think it is probably true that manufactured gas sales increased through the depression for residential house heating. It is very likely that it was almost four times as much in 1938 as in 1929, but, as I said with regard to refrigeration, the house heating load was pretty small in 1929.

The principal facts on which I based my conclusion as to rate of return are first, that it is a matter of general knowledge that electric cooking is pressing on gas cooking; second, I see every three months an index of gas and electric sales in the United States, and the gas sales have been increasing very slightly while the electric sales have shown good increases. I have no further information than
1232 that I just stated, namely that the quarterly index of gas sales has increased very slowly.

Cross-Examination by Mr. Slaff Resumed.

I hardly think that the sale of gas for house heating is an item of major importance in the gas industry. It is quite an undesirable load because it comes on the peak of the other load, and that taxes not only the producing or supplying facilities but the capacities of the mains.

Mr. Walter Beckjord is vice president and general manager of Columbia Gas and Electric Company. He is the new president of the American Gas Association. The Columbia Gas and Electric System operates large natural gas properties. I am not specifically aware of the article by Mr. Beckjord in the September 14, 1939, issue of Gas Age from which you have read and in which he states the following: "During the last 10 years the sale of gas for house heating has become an item of major importance to all branches of the industry. Always a large factor in the natural gas branch, special rates and sales activities for promoting house heating were initiated in the manufactured gas branch in 1915. In the beginning, the company growth was slow. In 1929 house heating customers in the manufactured gas branch totalled only 31,000 and consumed less than 4 percent of the total gas sales and contributed about 3 percent of the gross revenue of that branch. Nine years later, during 1938, the number of house heating customers had grown six-fold, to almost 200,000. House heating represented nearly 14 percent of the total gas sales, and house heating revenues were nearly 9 percent of the total revenues, three times the 1929 proportion. The number of customers using gas for house heating increased without exception during every year of the depression, and today more than 2,225,000 house heating customers are on our lines. There can be no question about the present and future importance of house heating to any gas company when it is realized that one-seventh of our customers are now utilizing gas for this purpose." I knew that there had been a substantial increase in house heating. I have the greatest respect for Mr. Beckjord's opinion. I would consider house heating important to the gas industry but not of major importance. As I explained, the load has some undesirable characteristics, and the fact that there was such a large increase in the volume, whereas the total sales increased so slowly would seem to indicate less load or even a loss of cooking load. I do not know that to be the fact. The fact that the companies are apparently going after the business would, up to a certain extent, indicate that it was a desirable part of their load, or that at least the desirable features outweighed in the companies' minds the undesirable features of the load. No, it would not indicate that attitude to the extent that the companies go after the load. It would be desirable to the extent of their capacity.

The house heating load has a very low load factor; and it comes on in the middle of winter when the other load is heavy. The amount that a company can take is limited by its production or supply capacity and the capacity of its system of mains. I do not think a company would go out to get business where the undesirable features outweighed the desirable features of that particular type of business.

If a particular company goes out to get house heating business, that is an indication that in its judgment the desirable features of that house heating business outweigh the undesirable features of that type of business for that company. That would apply to any company which goes out for that character of business.

I was not aware of the statement you quote from Mr. Young's article under the subcaption "Air Conditioning," in which he stated: "Air conditioning—the market for air conditioning is rapidly growing. Air conditioning equipment can be used to good advantage wherever people live, work, or play. The application of gas-operated absorption type direct dehumidification equipment as applied to the air conditioning field is making excellent progress. Air conditioning has been termed the nation's next great business. It carries a great opportunity for the gas industry." To the best of my information air conditioning by gas is insignificant at the present time. People in the public utilities business are now beginning to feel that the air conditioning market was overrated. The only practical type of gas apparatus that has been designed up to this time is something that cannot very well compete with the electric. I should say that the air conditioning market does not present a very attractive market for the future as far as the gas industry is concerned. In the present state of the art it certainly does not; and I know of no contemplated improvements or expected improvements.

1233 I am not aware that the article in the magazine Gas for August, 1939, at page 66, entitled "Gas Air Conditioning Serves Dallas Office Building," contained the statement that economy in operation of air conditioning apparatus may easily under-cost electricity as much as 75 per cent, and that gas-powered air conditioning has given a convincing demonstration of its ability through an installation in the Great National Life Building of Dallas, Texas. I am not familiar with the statement from that article, which you describe as the last statement, which (121) states: "Several other Dallas buildings have been air conditioned with natural gas power, and because of its feasibility, dependability, and economy, this fuel is expected to come into increasing demand."

I have not read the statement you quote from Mr. Young's article under the subcaption "Commercial and Industrial Use," and which was Mr. Young's final summarization as follows: "6—Commercial and Industrial Use. The future of commercial and industrial gas sales is decidedly bright. The steadily increasing demand and acceptance of gas in this field over the past nine years when despite adverse business conditions, sales increased almost 30 per cent, indicates the commanding position attained by the industry." I think that the future of industrial sales for manufactured gas is limited and the future for sales of natural gas is limited by the supply and the price at which it can be brought to the point of sale. I should not say that the future of commercial and industrial gas sales is decidedly bright. I should say it is moderately good. It is somewhat better than it was in the early part of 1938. I would call it an upturn but not an outstanding upturn. I suppose anything in the nature of an upturn is an upturn. I hesitated to use the word definite in my first answer because it appears to imply an outstanding upturn. I think the upturn was of such character as to be significant or indicative of the future, the immediate future; even though, while my recollection is not clear, I think that the weather conditions last January were more favorable for gas sales than January a year ago. I would say that 1938 was below a normal year for the gas business. There has been a definite upturn in the first quarter of 1939; and that upturn continues.

I do not know who Mr. Paul Ryan is. I do not know that he is the chief statistician of the American Gas Association. I have seen some of the statistical bulletins of the American Gas Association, but I cannot quote from them. I doubt if I have seen the copy of one of those bulletins for the year 1938 which you have handed me. That bulletin was published in October, 1939, after I had completed the preparation of my testimony in this case. I am not familiar with the paper entitled "The Natural Gas Industry—An Expanding Service" by Paul Ryan, chief statistician of the American Gas Association, which appeared in the magazine Gas for May, 1939, and which has been reprinted from that.

(At this point counsel for the Commission handed the document just mentioned to the reporter and requested that it be marked for identification. At the direction of the Examiner it was marked Exhibit 154 for identification.)

I cannot see why that would have added to my knowledge on the subject. I know perfectly well that the natural gas industry is expanding. I do not remember the facts about the difference in the temperature in 1938 as compared with the year 1937, but it is my impression that January, 1938, was warmer than January, 1939. According to my recollection the temperature in 1938 was about the same as in 1937. By the term "degree day" as used in the industry is meant one degree for one day below the normal temperature. That is the gas industry's standard measure of weather conditions. When I said January, 1938, was about the same as January, 1937, I was referring to temperatures in New York. I cannot say what the general condition throughout the country was.

1234 I could not have quoted the figure 5.2 per cent as representing the increase of revenues for the manufactured and natural gas utilities in May, 1939, over those of the same month of 1938, but I think that is about right. I think it would be reasonable to expect that the revenues for natural gas were up 8.4 per cent in that month in 1939 over the same month in 1938. The revenues were around 5 per cent less in 1938 than in 1937. I think you are right in stating that the revenues of the natural gas industry for the first six months of the year 1939 amounted to a gain of about 8.3 per cent over revenues for the first six months of the previous year.

Questions by the Examiner.

I said that I thought the gas sales in 1938 were on the order of 5 per cent under the sales in 1937. I had reference to the sales of both manufactured and natural gas.

Cross-Examination by Mr. Slaff Resumed.

In determining how the public appraises securities offered to the public or about to be offered to the public, one of the ways of doing it would be to consider what an investment banker, in whose judgment he has confidence, thinks about such types of securities. I know who the Mellon Securities Corporation are. I cannot say that I am very familiar with them. They are a very large investment house. I do not know who is president. I do not know who Mr. Frank R. Denton is. I never heard the name. If an article appeared in the American Gas Association Monthly for August, 1939, by Frank R. Denton and underneath his name was stated "President, Mellon Securities Corporation, Pittsburgh, Pennsylvania," I would have no doubt that Mr. Denton was president of that corporation. I am not aware of what Mr. Denton said in an article published in the American Gas Association Monthly, July-August, 1939, entitled "A Banker Analyzes Natural Gas Industry—Investment Values." I do not have a copy of that issue before me. I am not familiar with the opinions therein expressed.

It is a fact that the development and growth in use of natural gas has been enormous in the past twenty years. It is true, also, that with the increase of importance of natural gas has come a material change in the attitude of the banking and investment community toward that industry. I think, as stated in that article, that today the natural gas industry can borrow money at less cost than at any time in its history. Without checking the figures, I should think that the statement is true that during the period from 1929 down to the time of the article, July-August, 1939, the yield on bonds of some natural gas companies has been reduced twice as much as the yield on government securities. It is not the fact that the yield on some of the gas industry's securities is very comparable to that of some of the government issues, if the tax-free feature of the government bonds is considered. I must explain that I missed the word "comparable" in the question. I took the expression "very comparable" to mean somewhere near the same amount. My answer still is that the yields are not comparable.

It is true that there are some large blocks of natural gas securities held now by life insurance companies and other investors, whereas there were practically none a few years ago. It is a fact that the obligations of natural gas companies are today held in large blocks by insurance companies and other large investors, in contrast to their small investment in the securities of the natural gas industry a few years ago. That fact gives evidence of the improvement of the general credit rating of natural
1235 gas obligations. I think it is a fact that in spite of all the difficulties of the depression era, either financial or those connected with warm winters or poor business conditions, markets have been obtained by the industry, and the industry has established itself and in the past five years has reached the highest credit standing in its history. I have never read Mr. Denton's article, to which you refer, but I acknowledge his observation that: "We

may ask ourselves what are the principal reasons for the present high credit position of the natural gas industry and what it is that makes the banker and bond buyer so willing to advance funds to this industry. I believe the answer is that, in the first place, the banker, the bond buyer, and the consumer are thoroughly convinced of the value of natural gas as a fuel." I think he is correct also in his statement: "And in the second place, they,—that is, the banker, the bond buyer, and the consumer,—are convinced that adequate gas reserves exist and are available to the companies in which they are interested, and they realize that long distance transmission of gas from these reserves to the large markets is practicable."

1236 W. C. GILMAN, a witness for defendants, recalled for cross-examination, testified as follows:

(October 24, 1939)

Cross-Examination by Mr. Booth.

I have examined my testimony on direct. There is one place in my testimony where I was reading from my note book with reference to the taxes paid by Natural Gas Pipeline Company of America. I read off a subtotal of some $600,000, whereas the actual total was nearer $1,000,000. That is the only correction I wish to make.

I stated that after I left the Massachusetts Institute of Technology, I was employed by the General Electric. I was with that company in Schenectady, New York, where I was really in the illuminating engineering laboratories with the lighting engineering design department of that company. Later I was in the New York office of the company where I was sales engineer responsible for sales of electrical apparatus manufactured by the company to public utilities and industrial corporations. This was largely primarily lighting apparatus. In the later days of my stay with the company, we handled electric apparatus generally, except things like turbines and big pieces of apparatus.

From the employment with General Electric, I went to the Central Hudson Gas & Electric Corporation as manager of a division of the commercial department of that company. I reported to the commercial manager of the company and was in charge of the lighting division. I had a number of men who were responsible for designing lighting installations and sale of lighting installations to the customers of the company. I would not say that I had anything directly to do with the gas operations at that time; but I was on the staff of the commercial manager and attended all the meetings of the commercial department at which their program of sales with reference to both gas and electricity were discussed.

Later I was employed jointly by the Electric Bond & Share Company and the Carolina Power & Light Company in a rather general capacity, primarily in training to go abroad in the public utilities field. I never went abroad but went from that employment to the Equitable. With the latter company, my title was "Engineer, Treasurer's Office." It was my duty to make studies, investigations and reports for that company in connection with investments presently held or investments which we were contemplating making. I was the only man who was doing that kind of work for the Equitable. We had of course a railroad man. I probably had one or two clerks with me.

I could not repeat the figures as to the amounts represented by bonds, the preferred stocks, and common stocks in the total portfolio of the Equitable. I mean they were very large, running into the hundreds of millions of dollars. I can probably break down the public utilities portfolio in round numbers by saying that when I left the total holdings in public utility securities was somewhere around $300,000,000 or more, of which I estimate that the holdings of preferred stock were around $40,000,000. The difference between $40,00,000 and $300,000,000 would represent the bonds. The return earned by the Equitable
